Abstract

The paper introduces a stochastic model to forecast rainfall heights at site: the P.R.A.I.S.E. model (Prediction of Rainfall Amount Inside Storm Events). PRAISE is based on the assumption that the rainfall height $H_{i+1}$ accumulated on an interval $\Delta t$ between the instants $i\Delta t$ and $(i + 1)\Delta t$ is correlated with a variable $Z_i^{(v)}$, representing antecedent precipitation. The mathematical background is given by a joined probability density $f_{H_{i+1}Z_i^{(v)}}(h_{i+1}, z_i^{(v)})$ in which the variables have a mixed nature, that is a finite probability in correspondence to the null value and infinitesimal probabilities in correspondence to the positive values. As study area, the Calabria region, in Southern Italy, was selected, to test performances of the PRAISE model.

1 Introduction

Rainfall is the main input for all hydrological models such as, for example, rainfall-runoff models and for forecasting landslide induced by precipitation. In the last few years catastrophic rainfall events have occurred in the Mediterranean area, leading to floods, flash floods and shallow landslides (debris and mud flows). Consequently there is the need for the implementation of forecasting systems able to predict meteorological conditions leading to disastrous occurrences. Nowadays, for achieving this goal, meteorological and stochastic models are used. The former (Chuang et al., 2000; Palmer et al., 2000; Untch et al., 2006) can be viewed as valid qualitative-quantitative rainfall forecasting tools at 24, 48 and 72 h (of course, at these forecasting horizons an absolute precision is not required, but rather an order of magnitude) when these phenomena occur on a considerable spatial scale. Nevertheless, they cannot yet be regarded as providers of quantitative rainfall forecasts in the short term (6–12 h) to be used directly for forecasting systems, since the quantitative forecasting of precipitation, on the time and space scales of the hydrological phenomena, has not yet achieved the degree of
precision necessary to avoid either the non-forecasting of exceptional small-scale situations or the issuing of unwarranted alarms. Consequently, in order to perform short term real-time rainfall forecasts for small basins (i.e. with size ranging 100–1000 km²), temporal stochastic models appear more competitive. Stochastic processes are widely used in hydrological variables forecasting and, as regards at-site models, precipitation is considered as a time series with temporal coordinates at discrete points on a time axis. This set of temporal points can be known “a priori” (AutoRegressive Stochastic Models, Box and Jenkins, 1976; Salas et al., 1980; Bras and Rodriguez-Iturbe, 1984; Brockwell and Davis, 1987; Hipel and McLeod, 1994, Toth et al., 2000) or defined in a random way (Point Processes, Bartlett, 1963; Lewis, 1964; Kavvas and Delleur, 1981; Smith and Karr, 1983; Rodriguez-Iturbe et al., 1984; Rodriguez-Iturbe, 1986; Rodriguez-Iturbe et al., 1987; Cowpertwait, 1991; Onof and Wheater, 1994; Katz and Parlange, 1995, Cowpertwait et al., 1996; Sirangelo and Iiritano, 1997; Calenda and Napolitano, 1999; Montanari and Brath, 1999; Cowpertwait, 2004).

In the present work, a special kind of AutoRegressive model, named PRAISE (Prediction of Rainfall Amount Inside Storm Events), is described. It can be considered as a simple and useful tool for at site nowcasting precipitation, especially for applications in rainfall-runoff models, regarding small basins, and forecasting landslides, induced by rainfall, models. The paper is structured in three sections, excluding the introduction: in Sect. 2 the theoretical bases of the stochastic model are illustrated; while in Sect. 3 model calibration is shown; finally, Sect. 4 concerns the application of the model to the raingauge network of the Calabria region, in Southern Italy, with particular regard to the Cosenza raingauge.

## 2 The PRAISE model

In the PRAISE model, the rainfall depths $h_n$, cumulated over intervals $[(n-1) \Delta t, n\Delta t]$, are considered as a realisation of a weakly stationary stochastic process with discrete parameter $\{H_n; n \in I\}$, where $I$ indicates the integer numbers. The $H_n$ are non-negative
random variables of mixed type, with finite probability on zero value and infinitesimal probability on positive values. In the following the instant $i\Delta t=t_0$ is assumed as current time, so that the observed rainfall depths are with subscripts less or equal to $i$ and the probabilistic prediction will be referred to the rainfall depths with subscripts greater than $i$.

The main feature of the approach suggested in the PRAISE model is the identification of a random variable $Z_{i}^{(v)}$, a suitable function of the $v$ random variables $H_i, H_{i-1}, ..., H_{i-v+1}$, such that its stochastic dependence with the random variable $H_{i+1}$ describes the whole correlative structure of the process $\{H_n; n \in I\}$. Two steps are required to identify $Z_{i}^{(v)}$:

a) the individuation of the process “memory” extension $v$;

b) the optimal choice of the function depending on the random variables $H_i, H_{i-1}, ..., H_{i-v+1}$ defining $Z_{i}^{(v)}$.

After this, the PRAISE model provides the identification of the joint probability density $f_{H_{i+1}Z_{i}^{(v)}}\left(h_{i+1}, z_{i}^{(v)}\right)$ and its utilisation for the real time forecasting of rainfall depths during a storm event.

2.1 Extension of the “memory”

In the PRAISE model, the linear stochastic dependence between the random variable $H_{i+1}$ and the generic antecedent random variables $H_{i-j}$, $j=0,1,2,...$, is considered negligible when the correspondent sample coefficient of partial autocorrelation results less than a fixed value close to zero. The results given by this approach are similar to the more rigorous and less simple general method, in which the absence of a linear stochastic dependence should be tested verifying that the sample coefficient of partial autocorrelation, between such random variables, exhibits a value inside a confidence interval, which does not permit the rejection of the null value hypothesis for the correspondent theoretical quantity.

In order to determine the extension of the “memory” for the process $\{H_n; n \in I\}$,
the absence of significant partial autocorrelation must be checked for increasing values of \( \nu \). For each value of \( \nu \) must be verified the negligibility of all the sample coefficients of partial autocorrelation characterised by a couple of primary subscripts \( H_{i+1}, H_{i-v}; H_{i+1}, H_{i-v-1}; \ldots \) and by secondary subscripts \( H_i, H_{i-1}, \ldots, H_{i-v+1} \). In other words, partial autocorrelation must be evaluated in the following way:

\[
\rho_{H_{i+1} H_{i-v+1-m} \cdots H_i H_{i-v+1}} = \frac{\tilde{\lambda}_{(v+2)}(1)}{\sqrt{\tilde{\lambda}_{(v+2)}(1) \tilde{\lambda}_{(v+2)}(v+2)}} m = 1, 2, \ldots
\]

where \( \tilde{\lambda}_{(v+2)}(1) \), \( \tilde{\lambda}_{(v+2)}(1) \), and \( \tilde{\lambda}_{(v+2)}(v+2) \) are the cofactors of the Laurent edged matrix:

\[
\Lambda^{(v+2)} = \begin{bmatrix}
1 & \rho_1 & \rho_2 & \ldots & \rho_{v} & \rho_{v+m} \\
\rho_1 & 1 & \rho_1 & \ldots & \rho_{v-1} & \rho_{v+m-1} \\
\rho_2 & \rho_1 & 1 & \ldots & \rho_{v-2} & \rho_{v+m-2} \\
\vdots & \vdots & \vdots & \ldots & \vdots & \vdots \\
\rho_{v} & \rho_{v-1} & \rho_{v-2} & \ldots & 1 & \rho_1 \\
\rho_{v+m} & \rho_{v+m-1} & \rho_{v+m-2} & \ldots & \rho_1 & 1
\end{bmatrix}
\]

in which the autocorrelation \( \rho_{H_{i+1} H_{i-k+1}} \), depending only on lag \( k \) for the hypothesis of weakly stationary stochastic process, are indicated as \( \rho_k \).

Pratically, evaluation of \( \rho_{H_{i+1} H_{i-v+1-m} \cdots H_i H_{i-v+1}} \) must be performed using the sample coefficients of partial autocorrelation \( r_{H_{i+1} H_{i-v+1-m} \cdots H_i H_{i-v+1}} \), \( m=1, 2, \ldots, \) obtained by an observed sample \( h_1, h_2, \ldots, h_N \) of rainfall depths cumulated over time intervals of duration \( \Delta t \), after estimation of \( \rho_k \) by sample autocorrelation coefficients \( r_k \).

Finally, to estimate the extension of the “memory”, a simple way can be obtained introducing the sample maximum absolute scattering:

\[
\chi_r (\nu) = \max_{1 \leq m < \infty} \left| r_{H_{i+1} H_{i-v+1-m} \cdots H_i H_{i-v+1}} \right| m = 1, 2, \ldots
\]

The extension of the process “memory” can be assumed equal to the minimum value of \( \nu \) for which \( \chi_r (\nu) \) results less than a fixed critical value \( \chi_{r,cr} \).
2.2 Structure of the random variable $Z_{i}^{(v)}$

The criterion adopted in the PRAISE model to define a functional dependence between the random variable $Z_{i}^{(v)}$ and the random variables $H_{i}, H_{i-1}, ..., H_{i-v+1}$ is the maximisation of the coefficient of linear correlation $\rho_{H_{i+1}Z_{i}^{(v)}}$ between the same $Z_{i}^{(v)}$ and the random variable $H_{i+1}$. This choice allows, once identified the joint probability density $f_{H_{i+1}Z_{i}^{(v)}}(h_{i+1}, z_{i}^{(v)})$, the best prediction of rainfall depths $H_{i+1}$ during a storm event. If a functional relationship $Z_{i}^{(v)} = f_{01}(H_{i}, H_{i-1}, ..., H_{i-v+1})$ satisfies the criterion here adopted, then all the functions:

$$f_{ab}(H_{i}, H_{i-1}, ..., H_{i-v+1}) = a + b f_{01}(H_{i}, H_{i-1}, ..., H_{i-v+1})$$  (4)

with $a$ and $b$ generic constants, satisfy the same criterion. In other words, the criterion of maximisation of the coefficient of linear correlation between $Z_{i}^{(v)}$ and $H_{i+1}$ identifies a “class of functions”, defined by Eq. (4), with all the members equivalent for the purposes of the suggested model.

As regards the analytical form of the relationship linking $Z_{i}^{(v)}$ to $H_{i}, H_{i-1}, ..., H_{i-v+1}$, the more suitable choice is, clearly, the linear function:

$$Z_{i}^{(v)} = \beta + \sum_{j=0}^{v-1} \alpha_{j} H_{i-j}$$  (5)

In this condition, in fact, the coefficients of the linear relationship that maximises $\rho_{H_{i+1}Z_{i}^{(v)}}$ are simply the coefficients of the linear partial regression among $H_{i+1}$ and $H_{i}, H_{i-1}, ..., H_{i-v+1}$:

$$E\left(H_{i+1} | H'_{i}, H'_{i-1}, ..., H'_{i-v+1}\right) = \mu_{H} + \sum_{j=0}^{v-1} \alpha'_{j} H'_{i-j}$$  (6)
where \( E(.) \) is the expected value operator, \( \mu_H = E(H_n) \), constant value for every \( n \) because of the hypothesis of weakly stationary stochastic process, and \( H'_i = H_i - \mu_H, H'_{i-1} = H_{i-1} - \mu_H, H'_{i-v+1} = H_{i-v+1} - \mu_H \).

The \( \alpha'_j \) coefficients are evaluated as:

\[
\alpha'_j = -\frac{\tilde{\lambda}^{(v+1)}_{1(j+2)}}{\tilde{\lambda}^{(v+1)}_{11}}
\]  

(7)

where \( \tilde{\lambda}^{(v+1)}_{1(j+2)} \) and \( \tilde{\lambda}^{(v+1)}_{11} \) are the cofactors of the Laurent matrix:

\[
[\Lambda^{(v+1)}] = \begin{bmatrix}
1 & \rho_1 & \rho_2 & \ldots & \rho_v \\
\rho_1 & 1 & \rho_1 & \ldots & \rho_{v-1} \\
\rho_2 & \rho_1 & 1 & \ldots & \rho_{v-2} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\rho_v & \rho_{v-1} & \rho_{v-2} & \ldots & 1
\end{bmatrix}
\]  

(8)

These coefficients can be readily evaluated utilising again an observed sample \( h_1, h_2, \ldots, h_N \) of rainfall depths cumulated over time intervals of duration \( \Delta t \). However, it should be highlighted that, as a consequence of the non-negative character of the involved random variables, the coefficients \( \alpha'_j \) must satisfy the conditions \( \alpha'_j \geq 0 \) for \( j = 0, 1, \ldots, v - 1 \).

Moreover, the coefficients \( \alpha'_j \) identify, among all the possible linear combinations of \( H_i, H_{i-1}, \ldots, H_{i-v+1} \) variables, the one which maximizes the linear correlation coefficient with \( H_{i+1} \).

Then, definition of \( Z_i^{(v)} \) variable is very simple: let \( Z_i^{(v)} \) be a variable defined as:

\[
Z_i^{(v)} = \mu_H + \sum_{j=0}^{v-1} \alpha'_j H_{i-j}
\]  

(9)
it can be noted that it is equal to the conditional expected value
\[ E(H_{i+1} | H_i', H_{i-1}', ..., H_{i-\nu+1}') \]; rewriting Eq. (9) utilising \( H_i, H_{i-1}, ..., H_{i-\nu+1} \):

\[
Z_{*i}^{(v)} = \sum_{j=0}^{\nu-1} \alpha'_j H_{i-j} + \left( 1 - \sum_{j=0}^{\nu-1} \alpha'_j \right) \mu_H
\]

and introducing the standardised coefficients:

\[
\alpha_j = \frac{\alpha'_j}{\sum_{k=0}^{\nu-1} \alpha'_k}
\]  \hspace{1cm} (10)

for which the conditions \( 0 < \alpha_j \leq 1 \), for \( j=0, 1, ..., \nu - 1 \), and \( \sum_{j=0}^{\nu-1} \alpha_j = 1 \) are respected,

\( Z_{*i}^{(v)} \) can be expressed as:

\[
Z_{*i}^{(v)} = \sum_{k=0}^{\nu-1} \alpha'_k \sum_{j=0}^{\nu-1} \alpha_j H_{i-j} + \left( 1 - \sum_{j=0}^{\nu-1} \alpha'_j \right) \mu_H
\]  \hspace{1cm} (11)

Defining \( Z_i^{(v)} \) as:

\[
Z_i^{(v)} = \sum_{j=0}^{\nu-1} \alpha_j H_{i-j}
\]  \hspace{1cm} (12)

it is simple to verify that \( Z_{*i}^{(v)} \) and \( Z_i^{(v)} \) variables are connected by a linear transformation, identifying a class of function, defined by Eq. (4). Consequently the correlation coefficient \( \rho_{H_{i+1}, Z_i^{(v)}} \) is equal to \( \rho_{H_{i+1}, Z_{*i}^{(v)}} \).

Equation (12) shows that the random variable \( Z_i^{(v)} \) can be regarded as a weighted average of the \( \nu \) antecedent rainfall depths with weights expressed by the coefficients \( \alpha_j \).
2.3 Joint probability density \( f_{H_{i+1}Z_{i}^{(v)}} (h_{i+1}, z_{i}^{(v)}) \)

Keeping in mind the character of random variable of mixed type for \( H_{i+1} \) and, therefore, for \( Z_{i}^{(v)} \), the joint probability density \( f_{H_{i+1}Z_{i}^{(v)}} (h_{i+1}, z_{i}^{(v)}) \) must be written in the form:

\[
f_{H_{i+1}Z_{i}^{(v)}} (h_{i+1}, z_{i}^{(v)}) = p_{\cdot \cdot} \delta (h_{i+1}) \delta (z_{i}^{(v)}) + p_{\cdot +} f_{H_{i+1},0}^{(+ \cdot)} (h_{i+1}) \delta (z_{i}^{(v)}) + p_{+ \cdot} f_{H_{i+1}Z_{i}^{(v)}}^{(\cdot +)} (h_{i+1}, z_{i}^{(v)}) + p_{++} f_{H_{i+1}Z_{i}^{(v)}}^{(++)} (h_{i+1}, z_{i}^{(v)}) \tag{13}
\]

where \( \delta (.) \) is Dirac’s delta function, \( p_{\cdot \cdot}, p_{\cdot +}, p_{+ \cdot} \) and \( p_{++} \) indicate, respectively, \( \Pr \left[ H_{i+1} = 0 \cap Z_{i}^{(v)} = 0 \right] \), \( \Pr \left[ H_{i+1} > 0 \cap Z_{i}^{(v)} = 0 \right] \), \( \Pr \left[ H_{i+1} = 0 \cap Z_{i}^{(v)} > 0 \right] \) and \( \Pr \left[ H_{i+1} > 0 \cap Z_{i}^{(v)} > 0 \right] \), with, obviously, \( p_{\cdot \cdot} + p_{\cdot +} + p_{+ \cdot} + p_{++} = 1 \), and:

\[
f_{H_{i+1}Z_{i}^{(v)}}^{(+ \cdot +)} (h_{i+1}, z_{i}^{(v)}) \cdot dh_{i+1}d z_{i}^{(v)} = \Pr \left[ h_{i+1} \leq H_{i+1} < h_{i+1} + dh_{i+1} \cap z_{i}^{(v)} \leq Z_{i}^{(v)} < z_{i}^{(v)} + dz_{i}^{(v)} \ \left| \ H_{i+1} > 0 \cap Z_{i}^{(v)} > 0 \right. \right] \tag{14}
\]

\[
f_{H_{i+1},0}^{(+ \cdot)} (h_{i+1}) \cdot dh_{i+1} = \Pr \left[ h_{i+1} \leq H_{i+1} < h_{i+1} + dh_{i+1} \ \left| \ H_{i+1} > 0 \cap Z_{i}^{(v)} = 0 \right. \right] \tag{15}
\]

\[
f_{0,Z_{i}^{(v)}}^{(\cdot +)} (z_{i}^{(v)}) \cdot d z_{i}^{(v)} = \Pr \left[ z_{i}^{(v)} \leq Z_{i}^{(v)} < z_{i}^{(v)} + dz_{i}^{(v)} \ \left| \ H_{i+1} = 0 \cap Z_{i}^{(v)} > 0 \right. \right] \tag{16}
\]

A suitable mathematical form for \( f_{H_{i+1}Z_{i}^{(v)}}^{(++)} (h_{i+1}, z_{i}^{(v)}) \) may be achieved considering the standardised bivariate probability density of Moran & Downton (Kotz et al., 2000):

\[
f_{X,Y} (x, y) = \theta \exp [-\theta (x + y)] \int_{0}^{\infty} 2\sqrt{\theta (\theta - 1)} \, x y \quad x > 0, y > 0; \theta \geq 1 \tag{17}
\]
where \( I_0(u) \) is the modified Bessel function \( I \) of zero order (Abramowitz and Stegun, 1970).

An important peculiarity of this distribution is the capacity to reproduce any positive correlative structure between \( X \) and \( Y \) variables; they will be independent for \( \theta = 1 \) and connected in deterministic way for \( \theta \to +\infty \).

Applying a double power transformation:

\[
x = \alpha_{h,z}(h_{i+1})^{\beta_{h,z}} \quad h_{i+1} > 0; \alpha_{h,z} > 0, \beta_{h,z} > 0
\]

\[
y = \gamma_{h,z}(Z_i^{(v)})^{\delta_{h,z}} \quad Z_i^{(v)} > 0; \gamma_{h,z} > 0, \delta_{h,z} > 0
\]

and rewriting \( \theta \) as \( \theta_{h,z} \), the bivariate probability density so obtained, that can be called Weibull-Bessel, is given by:

\[
f_{H_{i+1},Z_i^{(v)}}^{(+,+)}(h_{i+1},Z_i^{(v)}) = \theta_{h,z} \alpha_{h,z} \beta_{h,z}(h_{i+1})^{\beta_{h,z}-1} \gamma_{h,z} \delta_{h,z} (Z_i^{(v)})^{\delta_{h,z}-1} \times \exp \left\{ -\theta_{h,z} \left[ \alpha_{h,z}(h_{i+1})^{\beta_{h,z}} + \gamma_{h,z} (Z_i^{(v)})^{\delta_{h,z}} \right] \right\} \times \left[ I_0 \left[ 2\sqrt{\theta_{h,z}^2 - 1} \right] \right]^{\beta_{h,z}} \gamma_{h,z} (Z_i^{(v)})^{\delta_{h,z}} \]

where \( h_{i+1} > 0, Z_i^{(v)} > 0; \alpha_{h,z} > 0, \beta_{h,z} > 0, \gamma_{h,z} > 0, \delta_{h,z} > 0, \theta_{h,z} \geq 1 \). As can be simply verified, the marginal probability densities of the Eq. (20) are Weibull densities with parameters \( \alpha_{h,z}, \beta_{h,z} \) and \( \gamma_{h,z}, \delta_{h,z} \). Consequently, moments of the distribution are immediate, as regards means and variances:

\[
\mu_{H_{i+1}}^{(+,+)} = E\left( H_{i+1} | H_{i+1} > 0 \cap Z_i^{(v)} > 0 \right) = \frac{\Gamma\left(1 + 1/\beta_{h,z}\right)}{\alpha_{h,z}^{1/\beta_{h,z}}}
\]
\[
\left( \sigma^2_{H_{i+1}} \right)^{(+,+)} = \text{var} \left( H_{i+1} | H_{i+1} > 0 \cap Z_i^{(v)} > 0 \right) = \frac{1}{\alpha^2_{h,z}} \left[ \Gamma \left( 1 + 2 \beta_{h,z} \right) - \Gamma^2 \left( 1 + 1 / \beta_{h,z} \right) \right] \quad (22)
\]

\[
\mu^{(+,+)}_{Z_i^{(v)}} = E \left( Z_i^{(v)} \mid H_{i+1} > 0 \cap Z_i^{(v)} > 0 \right) = \frac{\Gamma \left( 1 + 1 / \delta_{h,z} \right)}{\nu_{h,z}^{1/\delta_{h,z}}} \quad (23)
\]

\[
\left( \sigma^2_{Z_i^{(v)}} \right)^{(+,+)} = \text{var} \left( Z_i^{(v)} \mid H_{i+1} > 0 \cap Z_i^{(v)} > 0 \right) = \frac{1}{\nu_{h,z}^{2/\delta_{h,z}}} \left[ \Gamma \left( 1 + 2 / \delta_{h,z} \right) - \Gamma^2 \left( 1 + 1 / \delta_{h,z} \right) \right] \quad (24)
\]

Moreover, it can be proved that the coefficient of linear correlation between the random variables \( H_{i+1} \) and \( Z_i^{(v)} \), distributed according to the Eq. (20), is:

\[
\rho^{(+,+)}_{H_{i+1},Z_i^{(v)}} = \frac{2F_1 \left( -1/\beta_{h,z}, -1/\delta_{h,z}; 1; 1 - 1/\theta_{h,z} \right) - 1}{\sqrt{ \left[ \Gamma \left( 1 + 2 / \beta_{h,z} \right) \right] - 1} \cdot \left[ \Gamma \left( 1 + 2 / \delta_{h,z} \right) \right] - 1} \quad (25)
\]

where \( \Gamma \left( u \right) \) is the complete gamma function and \( 2F_1 \left( a, b; c; u \right) \) is the hypergeometric function (Abramowitz and Stegun, 1970). It must be pointed out how higher values of \( \theta_{h,z} \) parameter give higher values of \( \rho^{(+,+)}_{H_{i+1},Z_i^{(v)}} \).

As regards the couple of probability densities \( f_{H_{i+1},0}^{(+,+)} \left( h_{i+1} \right) \) and \( f_{0,Z_i^{(v)}}^{(\diamond,+)} \left( Z_i^{(v)} \right) \), the PRAISE model, in the form here employed, assumes again Weibull densities with parameters, respectively, \( \alpha_{h,*}, \beta_{h,*} \) and \( \gamma_{*,z}, \delta_{*,z} \):

\[
f_{H_{i+1},0}^{(+,+)} \left( h_{i+1} \right) = \alpha_{h,*} \beta_{h,*} \left( h_{i+1} \right)^{\beta_{h,*} - 1} \exp \left[ -\alpha_{h,*} \left( h_{i+1} \right)^{\beta_{h,*}} \right] \quad h_{i+1} > 0; \alpha_{h,*} > 0, \beta_{h,*} > 0 \quad (26)
\]

\[
f_{0,Z_i^{(v)}}^{(\diamond,+)} \left( Z_i^{(v)} \right) = \gamma_{*,z} \delta_{*,z} \left( Z_i^{(v)} \right)^{\delta_{*,z} - 1} \exp \left[ -\gamma_{*,z} \left( Z_i^{(v)} \right)^{\delta_{*,z}} \right] \quad Z_i^{(v)} > 0; \gamma_{*,z} > 0, \delta_{*,z} > 0 \quad (27)
\]
3 Parameter estimation

The parameter estimation for the bivariate probability density \( f_{H_i Z_i} (h_i, z_i) \) can be made on the basis of a sample \( h_1, h_2, \ldots, h_N \) of rainfall depths cumulated over time intervals of duration \( \Delta t \). First of all, starting from the sample \( h_1, h_2, \ldots, h_N \) and using the Eq. (12), a “sample” of \( Z_i \) can be calculated, namely \( Z_1, Z_2, \ldots, Z_N \). The probabilities \( p_{+,-}, p_{+,+}, p_{-,-} \) and \( p_{-,+} \), could be then estimated (according to the maximum likelihood method) by the frequencies \( N_{+,-}/N, N_{+,+}/N, N_{-,-}/N \) and \( N_{-,+}/N \) of the events \( H_{i+1} = 0 \land Z_i = 0, H_{i+1} > 0 \land Z_i = 0, H_{i+1} = 0 \land Z_i > 0 \) and \( H_{i+1} > 0 \land Z_i > 0 \) evaluated on the basis of the bivariate sample \( h_1, z_1; h_2, z_2; \ldots; h_N, z_N \). According to the method of moments, the parameters \( \alpha_{h,}, \beta_{h,}, \gamma_{z,}, \delta_{z,} \) could be estimated fitting means and standard deviations \( m_{H_{i+1}}^{(+,-)} \), \( s_{H_{i+1}}^{(+,-)} \) and \( m_{Z_i}^{(+,+)} \), \( s_{Z_i}^{(+,+)} \) of the bivariate sample \( h_1, z_1; h_2, z_2; \ldots; h_N, z_N \) restricted, respectively, by the conditions, \( h > 0, z = 0 \) and \( h = 0, z > 0 \).

\[
\hat{\beta}_{h,} = \beta_{h,} : \quad \Gamma \left( 1 + 2/\beta_{h,} \right) / \Gamma^2 \left( 1 + 1/\beta_{h,} \right) = 1 + \left( s_{H_{i+1}}^2 \right)^{(+,+)} / \left( m_{H_{i+1}}^{(+,+)} \right)^2 \tag{28}
\]

\[
\hat{\alpha}_{h,} = \left[ \Gamma \left( 1 + 1/\hat{\beta}_{h,} \right) / m_{H_{i+1}}^{(+,+)} \right]^{\hat{\beta}_{h,}} \tag{29}
\]

\[
\hat{\delta}_{z,} = \delta_{z,} : \quad \Gamma \left( 1 + 2/\delta_{z,} \right) / \Gamma^2 \left( 1 + 1/\delta_{z,} \right) = 1 + \left( s_{Z_i}^2 \right)^{(+,+)} / \left( m_{Z_i}^{(+,+)} \right)^2 \tag{30}
\]

\[
\hat{\gamma}_{z,} = \left[ \Gamma \left( 1 + 1/\hat{\delta}_{z,} \right) / m_{Z_i}^{(+,+)} \right]^{\hat{\delta}_{z,}} \tag{31}
\]
Similarly, the parameters of the Weibull-Bessel density, \( \alpha_{h,z}, \beta_{h,z}, \gamma_{h,z}, \delta_{h,z} \) and \( \theta_{h,z} \) could be estimated fitting the marginal means and standard deviations \( m_{H_{i+1}}^{(+,+)} \), \( s_{H_{i+1}}^{(+,+)} \), \( m_{Z_i}^{(v)} \) and \( s_{Z_i}^{(v)} \), and the coefficient of linear correlation \( r_{H_{i+1},Z_i}^{(+,+)} \) of the bivariate sample \( h_1, z_1^{(v)}; h_2, z_2^{(v)}; \ldots; h_N, z_N^{(v)} \) restricted by the condition \( h_j > 0, z_j^{(v)} > 0 \):

\[
\hat{\beta}_{h,z} = \beta_{h,z} : \quad \Gamma \left( 1 + 2 / \beta_{h,z} \right) / \Gamma^2 \left( 1 + 1 / \beta_{h,z} \right) = 1 + \left( s_{H_{i+1}}^{(v)} \right)^{(+,+)} / \left( m_{H_{i+1}}^{(+,+)} \right)^2 \tag{32}
\]

\[
\hat{\alpha}_{h,z} = \left[ \Gamma \left( 1 + 1 / \hat{\beta}_{h,z} \right) / m_{H_{i+1}}^{(+,+)} \right] \hat{\beta}_{h,z} \tag{33}
\]

\[
\hat{\delta}_{h,z} = \delta_{h,z} : \quad \Gamma \left( 1 + 2 / \delta_{h,z} \right) / \Gamma^2 \left( 1 + 1 / \delta_{h,z} \right) = 1 + \left( s_{Z_i}^{(v)} \right)^{(+,+)} / \left( m_{Z_i}^{(v)} \right)^2 \tag{34}
\]

\[
\hat{\gamma}_{h,z} = \left[ \Gamma \left( 1 + 1 / \hat{\delta}_{h,z} \right) / m_{Z_i}^{(v)} \right] \hat{\delta}_{h,z} \tag{35}
\]

\[
\hat{\theta}_{h,z} = \theta_{h,z} : \quad _2F_1 \left( -1 / \hat{\beta}_{h,z}, -1 / \hat{\delta}_{h,z} ; 1 ; 1 - 1 / \theta_{h,z} \right) = 1 + r_{H_{i+1},Z_i}^{(+,+)} s_{H_{i+1}}^{(v)} s_{Z_i}^{(v)} / m_{H_{i+1}}^{(+,+)} m_{Z_i}^{(v)} \tag{36}
\]

Equations (28)–(30)–(32)–(34)–(36) must be solved by numerical method (Press et al., 1988).

### 4 Application

Model calibration was performed using the hourly rain heights database of the telemetering raingauge network of the “Dipartimento per la Protezione Civile – Centro...”
Funzionale Meteoidrologico della Regione Calabria”. The raingauge network, located in the Calabria region, Southern Italy, is made up of 104 stations (Fig. 1). Approximately, 14 million hourly rainfalls form the database, of which about 7% are rainy. In order to respect the hypothesis of stationary process, only the data measured during the “rainy season”, 1 October–31 May has been used (De Luca, 2005)

The model parameters have been estimated for every raingauge. Subsequently, each parameter was mapped on the spatial regional domain by using a spline technique. The extension of the “memory”, determined by the technique described in the Sect. 2.1 fixing $\chi_{r,cr}=0.025$, has been found equal to $\hat{\nu}=8$ for all the tele-metering raingauges. An example of parameter mapping, referred to $\theta_{h,z}$ is represented in Fig. 2a, that shows greater values, and consequently higher values of $\rho_{H_{i+1},Z_{i}}^{(+,+)}$ correlation, located in the part of region characterized by greater altitude, as depicted by the comparison with the Digital Elevation Model of the Calabria region (Fig. 2b).

Considering hourly rain measurements of the Cosenza raingauge, covering a period of about 15 years, sample autocorrelogram and memory extension are depicted in Fig. 3.

The estimated coefficients $\hat{a}_{j}$, $j=1,2,\ldots,8$, given by Eqs. (7–10) once calculated the sample coefficients of the linear partial regression between $H_{i+1}$ and $H_{i}, H_{i-1}, \ldots, H_{i-\nu+1}$, are listed in Table 1. Finally, all the parameters of the bivariate probability density $f_{H_{i+1},Z_{i}^{(v)}}(h_{i+1},z_{i}^{(v)})$, estimated according to the methods described in section 3, are reported in Tables 2 and 3.

In Figure 4 empirical distribution functions of the variables $H_{i+1}|H_{i+1}>0 \cap Z_{i}^{(v)}>0$, $Z_{i}^{(v)}|H_{i+1}>0 \cap Z_{i}^{(v)}>0$, $H_{i+1}|H_{i+1}>0 \cap Z_{i}^{(v)}=0$ and $Z_{i}^{(v)}|H_{i+1}=0 \cap Z_{i}^{(v)}>0$, for the Cosenza raingauge, are depicted. To these empirical distributions, Weibull distribution functions, with parameters ($\alpha_{h,z}, \beta_{h,z}$), ($\gamma_{h,z}, \delta_{h,z}$), ($\alpha_{h,•}, \beta_{h,•}$) and ($\gamma_{•,z}, \delta_{•,z}$), are plotted. The plots indicate that the Weibull distributions are acceptable marginals for these variables.
4.1 Validation of the model

As regards rainfall forecasting, each simulation requires the knowledge of the rainfalls relative to the eight previous hours. Starting from these, simulations can be carried out for the successive hours. The temporal extension of the forecast should not exceed six hours. Beyond this limit the results become similar to the unconditional ones and, then, a model update by observed precipitation is necessary.

In the applications, using the Monte Carlo technique, the simulations are carried out repeating the process 10,000 times in order to have a large synthetic sample of rainfall heights for every forecasting hour. The Monte Carlo technique is adopted because of the complexity of determining analytical probabilistic distributions for rainfall heights relative to forecasting the hours successive to the first one. For these distributions, convolution operations should be required.

As an example, in this paper the applications relative to 19 November 1996 (Fig. 5) for the Cosenza rain gauge, and 16 December 2001 (Fig. 6) for the Catanzaro rain gauge are illustrated.

For every event, the real values of the precipitation have been compared with the percentiles 80%, 90% and 95% of the probabilistic distributions of every forecasting hour. Moreover, for every event the PRAISE model was applied shifting the starting point of forecasting for three successive hours.

The Figs. 5–6 show that rainfall heights of the real event fall between percentiles 80% and 90%. These results indicate the capability of the model to identify, for the forecast hours, statistical confidence limits containing the real rainfall heights.

5 Conclusions

This paper presents a new stochastic model named PRAISE to forecast rainfall heights at site. The mathematical background is characterized by a bivariate probability distribution, referred to the random variables $H_{i+1}$ and $Z^{(v)}_i$, representing rainfall in a generic
site and antecedent precipitation in the same site.

The peculiarity of PRAISE is the availability of the probabilistic distributions of rainfall heights for the forecasting hours, conditioned by the values of observed precipitation.

PRAISE was applied to all the telemetering raingauges of the Calabria region, in Southern Italy; the calibration model shows that the hourly rainfall series present a constant value of memory $\nu$ equal to 8 h, for every raingauge of the Calabria network. Moreover, analysing $\theta_{h,z}$ parameter mapping, it must be pointed out how higher values of $\rho_{H_i+1,Z_i}^{(+,+)}$ correlation are located in the part of region characterized by greater altitude.

The examples of validation, presented here, regarding the Cosenza and Catanzaro raingauges, indicate the capability of the model to identify, for the forecasting hours, statistical confidence limits containing the real rainfall heights. The PRAISE model therefore can be considered a very useful and simple tool for forecasting precipitation and consequently, using rainfall-runoff models or hydro-geotechnical models, floods or landslides, in planning and managing a warning system.
