23 **Abstract**

24 Within China's Loess Plateau there have been concerted revegetation efforts and
25 engineering measures over the last 50 years aimed at reducing soil erosion and land

26 degradation. As a result, annual streamflow, sediment yield and sediment concentration
27 have all decreased considerably. Human induced land use/cover change (LUCC) was the
28 dominant factor, contributing over 70% of the sediment load reduction, whereas the
29 contribution of precipitation was less than 30%. In this study, we use 50-year time series
30 data (1961-2011), showing decreasing trends in the annual sediment loads of fifteen
31 catchments, to generate spatio-temporal patterns in the effects of LUCC and precipitation
32 variability on sediment yield. The space-time variability of sediment yield was expressed
33 notionally as a product of two factors representing: (i) effect of precipitation and (ii)
34 fraction of treated land surface area. Under minimal LUCC, the square root of annual
35 sediment yield varied linearly with precipitation, with the precipitation-sediment load
36 relationship showing coherent spatial patterns amongst the catchments. As the LUCC
37 increased and took effect, the changes of sediment yield pattern depended more on
38 engineering measures and vegetation restoration campaign, and the within-year rainfall
39 patterns (especially storm events) also played an important role. The effect of LUCC is
40 expressed in terms of a sediment coefficient, i.e., ratio of annual sediment yield to annual
41 precipitation. Sediment coefficients showed a steady decrease over the study period,
42 following a linear decreasing function of the fraction of treated land surface area. In this
43 way, the study has brought out the separate roles of precipitation variability and LUCC in
44 controlling spatio-temporal patterns of sediment yield at catchment scale.

47 precipitation variability

48 **1 Introduction**

49 Streamflow and sediment transport are important controls on biogeochemical processes
50 that govern ecosystem health in river basins (Syvitski, 2003). Changes in soil erosion on
51 landscapes and the resulting changes in sediment transport rates in rivers have great
52 environmental and societal consequences, particularly since they can be brought about by
53 climatic changes and human induced land use/cover changes (LUCC) (Syvitski, 2003;
54 Beechie et al., 2010). Understanding the dominant mechanisms behind such changes at
55 different time and space scales is crucial to the development of strategies for sustainable
56 land and water management in river basins (Wang et al., 2016).

57 In recent decades, streamflows and sediment yields in large rivers throughout the world
58 have undergone substantial changes (Milly et al., 2005; Nilsson et al., 2005; Milliman et al.,
59 2008; Cohen et al., 2014). Notable decreases in sediment yields have been observed in
60 approximately 50% of the world's rivers (Walling and Fang, 2003; Syvitski et al., 2005).
61 Many studies have investigated the dynamics of streamflows and sediment yields at
62 different spatial and temporal scales (Mutema et al., 2015; Song et al., 2016; Gao et al.,
63 2016; Tian et al., 2016). In addition to climate variability, LUCC, soil and water
64 conservation measure (SWCM) and construction of reservoirs and dams have substantially
65 contributed to the sediment load reductions (Walling, 2006; Milliman et al., 2008; Wang et
66 al., 2011). While previous studies have certainly provided valuable insights into the
67 streamflow and sediment load changes, the distinctive roles of LUCC and precipitation
68 variability in changing sediment loads still need further investigation in large domains and
69 across gradients of climate and land surface conditions (Walling, 2006; Mutema et al.,

70 2015). A particularly useful approach to the development of generalizable understanding of
71 the effects of precipitation variability and LUCC is a comparative analysis approach
72 focused on extracting spatio-temporal patterns of sediment yields based on observations in
73 multiple locations within the same region, or even across different regions. This is
74 especially valuable and crucial in areas with severe soil erosion and fragile ecosystems, e.g.,
75 the Loess Plateau (LP) in China. This is the motivation for the work presented in this paper.

76 The LP lies in the middle reaches of the Yellow River (YR) Basin, and contributes
77 nearly 90% of the YR sediment (Wang et al., 2016). The historically severe soil erosion in
78 the LP is due to sparse vegetation, intensive rainstorms, erodible loessial soil, steep
79 topography and a long agricultural history (Rustomji et al., 2008). To control such severe
80 soil erosion, several SWCMs including terrace and check-dam construction, afforestation
81 and pasture reestablishment have been implemented since the 1950s (Yao et al., 2011; Zhao
82 et al., 2017). A large ecological restoration campaign, the Grain-for-Green (GFG) project
83 converting farmland on slopes exceed 15° to forest and pasture lands, was implemented in
84 1999 (Chen et al., 2015). Furthermore, the climate in the LP region has been showing both
85 warming and drying trends (i.e., increased potential evapotranspiration and reduced
86 precipitation) since the 1950s (Zhang et al., 2016).

87 These substantial LUCC have notably altered the hydrological regimes in the LP
88 combined with the climate change. Consequently, the sediment yields within the LP have
89 showed a predictable decline trend over the past 60 years (Zhao et al., 2017), resulting in
90 approximately a 90% decrease of sediment yield in the YR (Miao et al., 2010, 2011; Wang
91 et al., 2016). Many other studies have detected the influences of LUCC and precipitation

92 variability on sediment load changes within the LP. Rustomji et al. (2008) estimated that
93 the contributions of catchment management practices to the decrease of annual sediment
94 yield ranged between 64% and 89% for eleven catchments in the LP during 1950s-2000.
95 Zhao et al. (2017) examined the spatio-temporal variation of sediment yield from 1957 to
96 2012 across the LP. Zhang et al. (2016) pointed out that the combined effects of climate
97 aridity, engineering projects and vegetation cover change have induced significant
98 reductions of sediment yield between 1950 and 2008. Wang et al. (2016) found that
99 engineering measures for soil and water conservation were the main factors for the
100 sediment load decrease between 1970s-1990s, but large-scale vegetation restoration
101 campaigns also played an important role in reducing soil erosion since the 1990s.

102 On the basis of the outcomes of these previous studies, it is now generally accepted that
103 the largest reductions of sediment yield within the LP resulted from LUCC. However, this
104 is general knowledge covering the whole region, and given the significant variability of
105 climate and catchment characteristics across the LP (Sun Q et al., 2015; Sun W et al., 2015),
106 it is important to go further and explore how these might affect spatio-temporal patterns of
107 sediment yield. Exploration of these patterns is important for sustainable ecosystem
108 restoration and water resources planning and management within the LP. They also will
109 serve as the basis for future research aimed at the development of more generalizable
110 understanding of landscape and climate controls on sediment yields at the catchment scale.

111 Most of the sediment yield of the LP was produced in the Coarse Sandy Hilly
112 Catchments (CSHC) region (Fig. 1) in the central region of the LP, which supplied over 70%
113 of total sediment load in the YR, especially coarse sand (Rustomji et al., 2008). The CSHC

114 region was the focus of our efforts to investigate the variation of sediment load within the
115 LP. The specific objectives of this study therefore are to: (1) attribute the temporal changes
116 in sediment yield to changes in both precipitation variability and LUCC over the entire
117 study period (1961-2011) within the CSHC region, (2) extract spatio-temporal trends in
118 sediment yields on the basis of annual sediment yield data from 15 catchments within the
119 region, (3) separate the contributions of precipitation variability and fractional area of
120 LUCC to the observed spatio-temporal patterns of sediment yields, and pave the way for
121 more detailed process-based studies in the future.

122 **2 Materials and methods**

123 **2.1 Study area**

124 The CSHC region covers the area between the Toudaoguai to Longmen hydrological
125 stations in the mainstream of the YR (Fig. 1). The main stream that flows through the
126 CSHC region is 733 km long and covers an area of $12.97 \times 10^4 \text{ km}^2$, accounting for 14.8%
127 of the entire YR Basin. The CSHC region is characterized by arid to semi-arid climate
128 conditions. The annual precipitation in the CSHC region during 1961-2011 is 437 mm on
129 average, and varied from 580 mm in the southeast to lower than 300 mm in the northwest
130 (McVicar et al., 2007). The precipitation that occurs during the flood season
131 (June-September) is usually in the form of rainstorms with high intensity and accounts for
132 72% of the annual rainfall total. Correspondingly, about 45% of the annual runoff and 88%
133 of the annual sediment yield within the CSHC region are produced during the flood season.
134 The northwestern part of the CSHC is relatively flat while the southeastern part is more
135 finely dissected (Rustomji et al., 2008).

136 Fourteen main catchments along the north-south transect within the CSHC study area
137 were chosen for the study (Fig. 1). These catchments account for 57.4% of the CSHC area,
138 and contribute about 70% and 72% of streamflow and sediment load of the overall CSHC,
139 respectively, based on observed hydrological data during 1961-2011. Characteristics of
140 these catchments are shown in Table 1 and Fig. 2. It can be seen that the catchments
141 present strong climate and land surface gradients. The catchments in the northwestern part
142 (#1-6) have relatively lower mean annual precipitation ($380 \text{ mm} < \bar{P} < 445 \text{ mm}$, where \bar{P}
143 is mean annual precipitation over 1961-2011) and low growing season (April-October) LAI
144 ($0.41 < \text{LAI} < 0.48$, where LAI is the leaf area index), while the corresponding values for
145 catchments in the southeastern part (#7-14) are 470-570 mm and $0.63 < \text{LAI} < 3.26$,
146 respectively.

147 The entire CSHC region is considered as an additional “catchment” and it is also
148 examined independently. The streamflow and sediment load for the whole CSHC region
149 were taken to be equal to the differences of corresponding measurements between the
150 Toudaoguai and Longmen gauging station. The average annual precipitation, streamflow
151 and sediment load of the CSHC region during 1961-2011 was 437.27 mm, 33.30 mm and
152 5.17 Gt, respectively. Both the annual river discharge and sediment load across the CSHC
153 region showed significant decreasing trends (-0.82 mm yr^{-1} , $p < 0.001$ and -0.19 Gt yr^{-1} ,
154 $p < 0.001$, respectively) over the past five decades, whereas precipitation decreased only
155 slightly (-0.93 mm yr^{-1} , $p = 0.25$) (Fig. 3).

156 **2.2 Data**

157 Monthly streamflow and sediment load data during 1961-2011 were provided by the

158 Yellow River Conservancy Commission of China. Daily rainfall data from 1961 to 2011 at
159 66 meteorological stations in and around the CSHC region were obtained from the National
160 Meteorological Information Center of China. The spatially average of rainfall data was
161 carried out using the co-kriging interpolation algorithm with the DEM as an additional
162 input. With the hydro-meteorological data (including annual precipitation, P [mm],
163 streamflow, Q [mm], and sediment load, S [t]), specific sediment yield defined as $SSY=S/A$
164 [t km⁻²], where A is the drainage area of the hydrological station [km²], sediment
165 concentration defined as $SC=S/(Q.A)$ [kg m⁻³] and the sediment coefficient defined as
166 $C_s=SSY/P$ [t km⁻² mm⁻¹] were estimated for each catchment.

167 The mean catchment slope based on the ASTER GDEM data with a resolution of 30 m
168 and soil data (scale 1:500,000) were provided by the National Earth System Science Data
169 Sharing Infrastructure (<http://www.geodata.cn>). The land use information as at 1975, 1990,
170 2000 and 2010 was determined with Landsat MSS and TM remote sensing images at a spatial
171 resolution of 30 m. Six land use types were classified, i.e., forestland, cropland, grassland,
172 construction land, water body, and barren land. The LAI data during 1982-2011 were
173 obtained from the Global Land Surface Satellite (GLASS) NDVI Series with spatial
174 resolution of 1 km (www.landcover.org, Zhao et al., 2013). The total areas impacted by
175 various SWCMs (i.e., afforestation, grass plantation, terraces and check-dams) in each
176 catchment during 1960s-2000s were obtained from Yao et al. (2011).

177 **2.3 Methods**

178 **2.3.1 Trend test**

179 The non-parametric Mann-Kendall (M-K) test method proposed by Mann (1945) and

180 Kendall (1975) was used to determine the significance of the trends in annual
181 meteorological and hydrological time series. A precondition for using the MK test is to
182 remove the serial correlation of climatic and hydrological series. In this study, the
183 trend-tree pre-whitening (TFPW) method of Yue and Wang (2002) was used to remove the
184 auto-correlations before the trend test. There was no residual autocorrelation remaining
185 after performing the TFPW. A Z-statistic was obtained from the M-K test on the whitened
186 series. A negative value of Z indicates a decrease trend, and vice versa. The magnitude of
187 the slope of the trend (β) was estimated by (Sen, 1968; Hirsch et al., 1982):

$$188 \quad \beta = \text{Median} \left[\frac{x_j - x_i}{j - i} \right] \quad \text{for all } i < j \quad (1)$$

189 where x_i and x_j are the sequential data values in periods i and j , respectively.

190 **2.3.2 Attribution analysis of changes in sediment yield**

191 The time-trend analysis method was used to determine the quantitative contributions of
192 LUCC and precipitation variability to sediment yield changes. This method is primarily
193 designed to determine the differences in hydrological time series between different periods
194 (reference and validation periods) with different LUCC conditions (Zhang et al., 2011). In
195 this method, the regression equation between precipitation and sediment yield is developed
196 and evaluated during the reference period, and the established equation is then used to
197 estimate sediment yield during the validation period. The difference between measured and
198 predicted sediment yields during the validation period represents the effects of LUCC, and
199 the residual changes are caused by precipitation variability. The governing equations of the
200 time-trend analysis method can be expressed as:

$$201 \quad SSY_1 = f(P_1) \quad (2)$$

202
$$SSY'_2 = f(P_2) \quad (3)$$

203
$$\Delta SSY^{LUCC} = \overline{SSY}_2 - \overline{SSY}'_2 \quad (4)$$

204
$$\Delta SSY^{Pre} = (\overline{SSY}_2 - \overline{SSY}'_1) - \Delta SSY^{LUCC} \quad (5)$$

205 where SSY' is the predicted sediment yield, subscripts 1 and 2 indicate the reference and
 206 validation periods, respectively. \overline{SSY}'_1 and \overline{SSY}'_2 represent mean measured sediment yield
 207 during the reference and validation periods, respectively, and \overline{SSY}'_2 represents mean
 208 predicted sediment yield during the validation period. ΔSSY^{LUCC} and ΔSSY^{Pre} are sediment
 209 yield changes during the validation period associated with LUCC and precipitation
 210 variability, respectively. Rustomji et al. (2008) found that the square root of annual
 211 sediment yield in the catchments of the Loess Plateau was linearly related to annual
 212 precipitation. This was used in this study as the motivation to develop the
 213 precipitation-sediment yield relationship during the reference period:

214
$$\sqrt{SSY} = aP + b \quad (6)$$

215 In this study, the full data period of 1961-2011 was divided into three phases
 216 (1961-1969, 1970-1999 and 2000-2011). The first period was considered the reference
 217 period as the effects of human activities were slight and could be ignored (Wang et al.,
 218 2016). During the second stage, numerous SWCMs were implemented. For the third stage,
 219 a large ecological restoration campaign (GFG project) was launched in 1999.

220 **3 Results and discussion**

221 **3.1 Changes of land use/cover**

222 The CSHC region has undergone extensive LUCC caused by the implementation of
 223 SWCM and vegetation restoration projects (e.g., the GFG project). Fig. 4 shows the

224 distribution of land use types of the CSHC region in 1975, 1990, 2000 and 2010. More than
225 90% of the whole area is occupied by the cropland, forestland and grassland. The area of
226 cropland decreased by 26.72% and forestland increased by 53.15%, and there was no
227 obvious change for the area of grassland (increase of 4.21%) in the CSHC region from
228 1975-2010. The majority of changes occurred during 2000-2010 due to the GFG
229 (reforestation) project (26.67% decrease and 36.21% increase for cropland and forestland,
230 respectively). The transition from cropland to forestland was greater in the catchments of
231 the southeastern part (especially in catchments #7-#9) than that in the northwestern part
232 (Fig. 4). From 1975 to 2000, the increase of forestland was 26.34% and 4.55% in the
233 southeastern and northwestern part, respectively, and the change of cropland was negligible
234 (only -0.39% and 0.22%, respectively). During 2000-2010, the forestland increased by
235 47.79% and 18.30%, and the cropland decreased by 44.84% and 21.04% in the
236 southeastern and northwestern part, respectively.

237 The SWCMs implemented in the LP included both biotic treatments (e.g., afforestation
238 and grass-planting) and engineering measures (e.g., construction of terrace and check-dam
239 and gully control projects). Afforestation, grass-planting and construction of terraces are
240 seen as the slope measures, while building of check-dams and gully control projects are the
241 measures on the river channel. Although the utilized area of engineering measures was
242 much smaller than the biotic treatments, they can immediately and substantially trap
243 streamflow and sediment load. The fraction of the treated area (area treated by erosion
244 control measures relative to total catchment area) within the CSHC increased from 3.95%
245 in the 1960s to 28.61% in the 2000s (Fig. 5). The increase of the treated area was greatest

246 during the 1980s as a result of comprehensive management of small watersheds and during
247 the 2000s due to the GFG project since 1999. Some decreases in these areas occurred
248 during the 1990s as some of the erosion control measures undertaken were then
249 subsequently destroyed.

250 The growing season LAI of the whole CSHC region changed from 0.74 during
251 1982-1999 to 0.81 during 2000-2011, an increase of 10.16% (Fig. 5). The LAI did not
252 show significant increase during 1982-1999 (0.003 yr^{-1} , $p=0.11$), and it increased
253 significantly during 2000-2011 (0.024 yr^{-1} , $p<0.01$). The increase of growing season LAI
254 during 1982-2011 was greater for the catchments in the southeastern part (0.009 yr^{-1})
255 compared to the northwestern part (0.004 yr^{-1}), especially after 2000 (Fig. 6). From the
256 period of 1982-1999 to 2000-2011, the average increase of growing LAI of the fourteen
257 sub-catchments is 0.088 yr^{-1} ($0.010\text{-}0.183 \text{ yr}^{-1}$), with the increase of 0.114 yr^{-1} and 0.053
258 yr^{-1} in the southeastern and northwestern part, respectively.

259 **3.2 Trends of hydro-meteorological and sediment yield variables**

260 Table 2 shows the trends in annual P , Q , SSY , SC and C_s of the fifteen catchments during
261 1961-2011. The annual P showed a decline trend in all catchments but is only significant in
262 the Xinshui and Zhouchuan catchments ($p<0.05$). The annual Q , SSY , SC and C_s showed
263 significant decreasing trends in all the catchments, and most of the decreases were at the
264 0.001 significance level. For the fourteen sub-catchments, the average decrease rates of
265 annual values of Q , SSY , SC and C_s were 0.86 mm yr^{-1} ($0.24\text{-}1.66 \text{ mm yr}^{-1}$), 190.06 t km^{-2}
266 yr^{-1} ($26.47\text{-}398.82 \text{ t km}^{-2} \text{ yr}^{-1}$), $2.73 \text{ kg m}^{-3} \text{ yr}^{-1}$ ($0.69\text{-}4.70 \text{ kg m}^{-3} \text{ yr}^{-1}$) and $0.38 \text{ t km}^{-2} \text{ mm}^{-1}$
267 yr^{-1} ($0.04\text{-}0.87 \text{ t km}^{-2} \text{ mm}^{-1} \text{ yr}^{-1}$), respectively. For the whole CSHC region, the

268 corresponding change rates of Q , SSY , SC and C_s were -0.85 mm yr^{-1} , $-131.52 \text{ t km}^{-2} \text{ yr}^{-1}$,
269 $-2.06 \text{ kg m}^{-3} \text{ yr}^{-1}$ and $-0.27 \text{ t km}^{-2} \text{ mm}^{-1} \text{ yr}^{-1}$, respectively. The annual average reductions in
270 the whole CSHC region are equivalent to 2.56%, 3.30%, 2.01% and 3.07% of the mean
271 annual values of Q , SSY , SC and C_s , respectively.

272 The mean and the coefficient of variation, C_v , representing inter-annual variability of
273 annual values of P , Q , SSY , SC and C_s of the fifteen catchments during the three phases
274 (reference period-1, period-2 and period-3) are shown in Fig. 7. Compared to standard
275 deviation, the C_v value was better able to indicate the inter-annual variability of precipitation,
276 streamflow and sediment load among the catchments with distinct different average values.
277 Compared to the reference period, the mean annual precipitation decreased by 11.73%
278 (6.36%-15.69%) and 10.64% (5.88%-16.7%) on average in period-2 and period-3,
279 respectively. From period-2 to period-3, the change of mean annual precipitation was slight
280 (increased by 1.32% on average) with a decrease of 2.45%-5.87% in four catchments and an
281 increase in the remaining catchments (0.35%-8.29%). The variability of annual P also
282 decreased as indicated by the reductions of C_v values during period-2 and period-3 (Fig. 7a).
283 In contrast to annual P , the reductions of mean annual Q , SSY , SC and C_s were clearly more
284 evident. With respect to the reference period, the reduction was 34.41% (9.45%-54.72%),
285 48.02% (17.98%-67.61%), 24.20% (-9.93%-47.77%) and 39.31% (4.64%-63.5%) for Q , SSY ,
286 SC and C_s during period-2, and the decreasing rate was even more in period-3 with values of
287 64.82% (36.72%-84.19%), 88.23% (64.94%-97.64%), 67.81% (17.28%-91.12%) and 85.85%
288 (63.51%-96.97%), respectively. C_v of annual Q increased in eight catchments, with the
289 remaining ones showing decreasing trends (Fig. 7b), while C_v values for SSY , SC and C_s

290 increased in all catchments (Figs 7c-7e). The above results indicate the substantially different
291 behaviors of the changes among precipitation, streamflow and sediment load.

292 **3.3 Quantitative attribution of sediment yield decline**

293 The effects of precipitation change and LUCC on sediment yield reductions in period-2 and
294 period-3 were quantified using Eqs. (2-6) and the results are shown in Fig. 8. The analysis
295 showed that both decreased precipitation and increased area treated with erosion control
296 measures contributed to the observed sediment load reduction, and that LUCC played the
297 major role. On average, the LUCC and precipitation change contributed 74.39% and
298 25.61%, respectively, to sediment load reduction from the reference period to period-2, and
299 their contributions were, respectively, 88.67% and 11.33% to sediment load reduction from
300 the reference period to period-3, respectively. The effect of LUCC in period-3 was greater
301 than that in period-2 as the land use/cover (see Figs. 4-5) and vegetation coverage (see Fig.
302 6) had undergone substantial changes due to the ecological restoration campaigns launched
303 during period-3. From period-2 to period-3, the contribution of precipitation was negative
304 for sediment yield reduction in eleven catchments where the annual precipitation slightly
305 increased during these two periods, and thus the contribution of LUCC was larger than 100%
306 (Fig. 8c). In the remaining four catchments, the average contribution of LUCC increased to
307 83.96%.

308 In broad terms there are two factors that govern annual sediment yield of a catchment:
309 precipitation and landscape properties (soil, topography and vegetation). Precipitation is the
310 primary driver of runoff and, therefore, directly influences the sediment transport capacity
311 of streamflow and sediment yield at the catchment scale. Higher precipitation means higher

312 streamflow, which is the immediate driver of erosion and sediment transport. Landscape
313 properties not only have an impact on the volume or intensity of streamflow, but also
314 determine the erodibility of the soil. We have investigated the correlations between the
315 potential factors (precipitation, percentage area of afforestation, pasture plantation,
316 terracing, check-dams and construction land, and LAI) and sediment yield change between
317 different stages (see Table 4). It was found that check-dam construction was the dominant
318 factor for sediment yield reduction from reference period to period-2, and pasture
319 plantation and check-dam construction acted the dominant factors for sediment yield from
320 reference period to period-3. The increase of precipitation mitigated the reduction of
321 sediment yield to some degree from period-2 to period-3.

322 Based on the above results, in the reference period before LUCC took effect, the
323 variation of *SSY* mainly depends on precipitation, and any spatial patterns of *SSY* among
324 catchments may be controlled by differences in annual precipitation and land surface
325 conditions. During the validation period (period-2 and period-3) with LUCC increased and
326 took effect, *SSY* decreased considerably whereas the decrease of precipitation was
327 insignificant, LUCC contributing over 70% of the sediment yield reduction. In this case,
328 the temporal changes of *SSY* depend more on the fraction of treated surface area and
329 precipitation possibly might play a secondary role. The spatial pattern of the impacts of
330 precipitation on sediment yield is dependent on the landscape properties among catchments.
331 Guided by this framework, we next organize the data analysis to generate separate spatial
332 and temporal patterns that constitute the respective components of the spatio-temporal
333 patterns.

334 **3.4 Spatial-temporal pattern of the impacts of precipitation on sediment yield**

335 The regression equations of $\sqrt{SSY} = aP + b$ are shown in Table 3, and the spatial
336 distributions of precipitation-sediment relationships during the three stages are shown in
337 Fig. 9. During the reference period, most of the catchments showed strong correlation
338 between precipitation and sediment yield. The coefficient of determination (R^2) ranged
339 from 0.27 to 0.87, and the correlation was significant in eleven catchments ($p < 0.05$) (Table
340 3). Overall, the regressed equations were significant for most of the catchments, and were
341 suitable for estimating the relative contributions of LUCC and precipitation variability to
342 sediment yield changes. Furthermore, the precipitation-sediment yield relationship varied
343 from catchment to catchment and showed a spatial pattern. The correlation coefficient
344 between precipitation and sediment yield was greater for catchments in the northwestern
345 part with average R^2 value of 0.75 and p value of 0.007 compared to those in the
346 southeastern part where the average R^2 and p values were 0.48 and 0.059, respectively
347 (Table 3). Based on the slopes of the regression equations between annual precipitation and
348 sediment yield, the fourteen catchments were classified into four groups (Group-1: $a > 0.3$,
349 Group-2: $0.2 < a < 0.3$, Group-3: $0.1 < a < 0.2$ and Group-4: $0 < a < 0.1$), which indicate that the
350 sediment production capability of annual precipitation is different among the catchments
351 (Fig. 9a). The four catchments in the northwestern part had the greatest slopes of $a > 0.3$ and
352 the Shiwang catchment had the lowest slope of 0.07. Most of the catchments in the
353 southeastern part were in the second group of $0.2 < a < 0.3$.

354 Compared to the reference period, the correlation between precipitation and sediment
355 yield during the period-2 decreased in the catchments, as indicated by the reductions of R^2

356 value in Table 3. The slope of the regression line in the period-2 decreased in most of the
357 catchments with respect to the reference period, except in some catchments (e.g., Huangfu,
358 Gushan and Kuye) with slight increase. Furthermore, the spatial patterns of the
359 precipitation-sediment yield relationship during these two periods were somewhat different
360 (Figs. 9a and 9b).. From the reference period to period-2, Jialu catchment moved from
361 Group-1 to Group-2 and five catchments moved from Group-2 to Group-3.

362 During period-3, the correlation between precipitation and sediment yield was much
363 weaker compared to that during the reference period and period-2 (Table 3). The
364 relationship between precipitation and sediment yield was non-significant in all of the
365 catchments (Table 3). The slope of the regression line during period-3 decreased sharply
366 (Table 3), and for six catchments the regression slope (five in the north-western part and
367 one in the south-eastern part) was even negative (Fig. 9c). This result indicates that the
368 sediment production capability of annual precipitation reduced greatly during period-3, and
369 the increase of precipitation amount in some catchments did not lead to an increase of
370 sediment yield. Furthermore, the spatial pattern of precipitation-sediment relationship
371 during period-3 was much different from those during the reference period and period-2
372 based on comparisons of Fig. 9c with Figs. 9a-9b. There were only three groups with two
373 catchments having regression slopes of $0.1 < a < 0.2$, six catchments having regression slopes
374 of $0.1 < a < 0.2$ and six catchments having negative regression slopes.

375 The aforementioned analysis of the precipitation-sediment yield relationship in
376 different periods clearly indicates that the impacts of precipitation on sediment yield
377 declined with time, and the impacts were different among catchments, with a clear spatial

378 pattern. The effects of precipitation on the sediment yield were greater in the north-western
379 part compared to those in the south-eastern part. The decreased effects of precipitation on
380 sediment yield with time were consistent with the significant reductions of sediment
381 coefficient (Table 2) and the decreased contribution of precipitation to sediment load
382 reduction (25.61% and 11.33% in period-2 and period-3, respectively). During period-2,
383 the LUCC were mainly induced by SWCM, especially engineering measures. During
384 period-3, the combined effects of substantial vegetation cover and conservation measures
385 further weakened the effects of precipitation on sediment load reduction.

386 Differences in catchment characteristics, including land use/cover, soil properties and
387 topography, as well as precipitation characteristics, are clearly the reason for the spatial
388 patterns in the precipitation-sediment yield relationship (Morera et al., 2013; Mutema et al.,
389 2015). The lower vegetation cover was the main reason for the greater effects of
390 precipitation on sediment yield in the northwestern part. To fully explore this, the mapping
391 of information of catchment characteristics into sediment yield models and simulations
392 under different climate scenarios are needed (Ma et al., 2014; Achete et al., 2015). In this
393 context, the inter-annual and intra-annual patterns of variability of precipitation, including
394 the distribution of storm events, may also contribute to the observed spatial patterns of
395 precipitation-sediment yield relationship.

396 As LUCC took effect during period-2 and period-3, and despite the much reduced role
397 of precipitation in driving changes in sediment yield, within-year temporal rainfall patterns
398 did play an important role in the observed changes of sediment yield, given that most of the
399 sediment yield was produced during a few key storm events. The correlation between

400 sediment yield and storm events with daily precipitation amount larger than 20 mm
401 (including storm numbers, precipitation amount of storms) in the CSHC region during
402 different decades were investigated (see Table 5). The analysis showed that the sediment
403 yield was significantly correlated with storm numbers in the 1960s, 1970s and 1980s
404 ($p<0.05$), and precipitation amount of storms in the 1960s and 1970s ($p<0.05$). This result
405 indicated the critical role of storm events in sediment yield, especially during the periods
406 before substantial LUCC took effect.

407 Looking into this in more detail, taking the Yanhe catchment as an example, the
408 precipitation amount during the rainy season (May-October when sediment load was
409 measured) in 2003 and 2004 was 514.31 mm and 389.05 mm, respectively, whereas the
410 sediment load in 2003 (2427.37×10^4 t) was about over four times of that in 2004
411 (590.04×10^4 t). As shown in Fig. 10, there were six days with precipitation amounts over
412 20 mm and the maximum daily precipitation amount on 25th August was 27.85 mm in
413 2003, and the values in 2004 were five days and 46.34 mm on 10th August. Furthermore,
414 heavy rainfall events were distributed in every month in 2003, whereas they were
415 concentrated in July and August in 2004. There were five evident peaks of sediment load
416 with the sum of 1646.24×10^4 t (67.82% of annual total) in 2004, especially the one on 10th
417 August produced 784.53×10^4 t sediment load (32.32% of annual total) (Fig. 10b). In
418 contrast, there were three peaks of sediment load in 2003, and the maximum value was
419 only 139.97×10^4 t (Fig. 10a). Therefore, apart from annual precipitation amounts,
420 within-year rainfall patterns should also be considered to investigate the effects of
421 precipitation on temporal-spatial changes of streamflow and sediment load.

422 **3.5 Spatial-temporal pattern of the impacts of land use/cover on sediment yield**

423 The sediment load reductions in the LP were primarily caused by the LUCC and the
424 implementation of SWCM. The cropland area decreased 9733.91 km² (8.73% of region area)
425 and the forestland area increased 7662.50 km² (6.87% of region area) from 1975 to 2010.
426 Most of the increase in forestland area was converted from cropland area induced by the GFG
427 or reforestation project. As a result of the land use change, vegetation cover increased greatly
428 and it substantially contributed to the decreases of runoff and sediment production. The
429 SWCMs, such as afforestation and engineering measures were the major interventions in the
430 study area to retain precipitation and consequently reduce streamflow and sediment load.
431 Establishing perennial vegetation cover was considered as one of the most effective measures
432 to stabilize soils and minimize erosion (Farley et al., 2005; Liu et al., 2014). It was reported
433 that both runoff coefficient and sediment concentration of catchments in the LP decreased
434 significantly and linearly with the vegetation cover (Wang et al., 2016). The engineering
435 structures mainly included creation of terrace and building of check-dams and reservoirs,
436 which reduced flood peaks and stored water and sediment within the catchment. There were
437 about 110, 000 check-dams in the LP which trapped about 21 billion m³ of sediment during
438 the past six decades (Zhao et al., 2017). Over time, the effectiveness of engineering measures
439 decreased as they progressively fill with sediments, and vegetation restoration must in future
440 play a greater role in control of soil erosion for the LP.

441 To quantify the effects of SWCM on sediment load reduction, the relationship between
442 the decadal sediment coefficient and the fraction of area treated with erosion control
443 measures in the 15 catchments was analysed and the results are presented in Table 6. The

444 decadal sediment coefficient (\overline{SC}) decreased linearly with the fraction of treated land surface
445 area (A_c) in all catchments:

$$446 \quad \overline{SC} = -mA_c + n \quad (7)$$

447 The correlation was significant in eleven catchments ($p < 0.05$) with R^2 ranging from 0.78
448 to 0.99 (Table 6). The effects of SWCM on sediment load change show a spatial pattern. The
449 correlation between sediment coefficient and conservation measures was stronger in
450 catchments located in the north-western part compared to that in the south-eastern part (Table
451 6). Based on the slope of the regression equation between the sediment coefficient and
452 fraction of the treated area, the catchments were classified into three groups in Fig. 11
453 (Group-1: $0.8 < m < 1.2$, Group-2: $0.4 < m < 0.8$ and Group-3: $0 < m < 0.4$), which indicated that the
454 degree of sediment load impacted by conservation measures was different among the
455 catchments. The average m value was 0.73 and 0.37 for the catchments in the north-western
456 and south-eastern part, respectively, Half of the catchments in the north-western part were in
457 Group-1 and the other half were in Group-2, whereas six of the eight catchments in the
458 south-eastern part were in Group-3 with lowest regression slope.

459 **4 Conclusions**

460 The Loess Plateau has undergone major changes in land use/land cover over the last 50
461 years as part of a concerted effort to cut back on soil erosion and land degradation and
462 sediment yield of rivers. These included terrace and check-dam construction, afforestation,
463 and pasture reestablishment. Over the same period the region has also experienced some
464 reduction in rainfall, although this is relatively insignificant. Through analyses of
465 hydrological and sediment transport data, this study has brought out the long-term

466 decreasing trends in sediment loads across fifteen large sub-catchments located in the
467 region. The study was particularly aimed at extracting spatio-temporal patterns of sediment
468 yield and attributing these patterns to the broad hydro-climatic and landscape controls.

469 Over the study period (1961-2011), the total area undergoing erosion control treatment
470 went up from only 4% to over 30%. This included to decrease of cropland by 27%, increase
471 of forestland by 53% and grassland by 4% from 1975-2010. Over the same period annual
472 precipitation decreased by not more than 10%. As a result of the erosion control measures,
473 over the entire 50-year period, there have been major reductions in streamflow (65%),
474 sediment yield (88%), sediment concentration (68%) and sediment efficiency, i.e., annual
475 sediment yield/annual precipitation (86%).

476 The observed data in the 15 study catchments also exhibits interesting spatio-temporal
477 patterns in sediment yield. The study attempted to separate the relative contributions of
478 annual precipitation and LUCC to these spatio-temporal patterns. Before LUCC took effect
479 the data indicates a linear relationship between square root of annual sediment yield and
480 annual precipitation in all 15 catchments, with highly variable slopes of the relationship
481 between the catchments, which exhibited systematic spatial patterns, in spite of some
482 scatter. As LUCC increased and took effect, the scatter increased and the slopes of the
483 sediment yield vs precipitation relationship became highly variable and lost any predictive
484 power. The study then looked at the controls on sediment coefficient instead of sediment
485 yield (thus eliminating the effect of precipitation and enabling a direct focus on landscape
486 controls). The results of this analysis found that sediment coefficient was heavily
487 dependent on the area under land use/cover treatment, exhibiting a linear (decreasing)

488 relationship. Even here, there was a considerable variation in the slope of the relationship
489 between the 15 catchments, which exhibited a systematic spatial pattern.

490 Preliminary analyses presented in this study suggest that much of the sediment yield in
491 the LP may be caused during only a few major storms. Therefore, the seasonality and
492 intra-annual variability of precipitation may play important roles in annual sediment yield,
493 which may also explain the spatial patterns of sediment yield and the effects of the various
494 LUCC. Also, the precipitation threshold for producing sediment yield would have increased
495 greatly as a result of SWCM and vegetation restoration in the LP. Exploration of these
496 questions in detail will require a more physically based model that can account for fine
497 scale rainfall variability and catchment characteristics. This is the next immediate step in
498 our investigations, and will be reported on in the near future.

607 **Figure 1.** Location of the studied catchments in the Coarse Sandy Hilly Catchments
608 (CSHC) region within the Loess Plateau.

609 **Figure 2.** Spatial distribution of (a) annual precipitation (1961-2011), (b) growing season
610 leaf area index (LAI, 1982-2011), (c) soil type and (d) slope in the study area.

611 **Figure 3.** Annual precipitation, streamflow and sediment load for the whole CSHC region
612 during 1961-2011.

613 **Figure 4.** Land use and cover of the study area in (a) 1975, (b) 1990, (c) 2000 and (d)
614 2010.

615 **Figure 5.** The changes of soil and water conservation measures area and growing season
616 LAI in the study area.

617 **Figure 6.** Long-term trends in growing season LAI changes over (a) 1982-2011, (b)
618 1982-1999 and (c) 2000-2011 in the study area. Inset in each figure shows the
619 frequency distribution of the LAI trends.

620 **Figure 7.** The changes of (a) precipitation, (b) streamflow, (c) sediment yield, (d) sediment
621 concentration and (e) sediment coefficient during different stages (1961-1969,
622 1970-1999 and 2000-2011).

623 **Figure 8.** Contributions of precipitation and land use/cover to reductions of sediment load
624 from (a) reference period (P1) to period-2 (P2), (b) reference period (P1) to period-3 (P3)
625 and (c) period-2 (P2) to period-3 (P3).

626 **Figure 9.** Spatial distribution of slope a in the regression equation $\sqrt{SSY} = aP + b$ during
627 (a) reference period (1961-1969), (b) period-2 (1970-1999) and (c) period-3

628 (2000-2011). SSY is specific sediment yield, and P is precipitation.

629 **Figure 10.** Daily precipitation and sediment load of the Yanhe catchment during rainy
630 season (May-October) in (a) 2003 and (b) 2004.

631 **Figure 11.** Spatial distribution of slope m in the regression equation $\overline{SC} = -mA_c + n$. \overline{SC} is
632 the decadal average sediment coefficient, and A_c is the percentage of the area affected by
633 soil and water conservation measures in the catchments.

Table 1. Long-term hydrometeorological characteristics (1961-2011) and growing season leaf area index (LAI) (1982-2011) of the studied catchments in the Loess Plateau.

Table 4. The regression models for sediment yield change (ΔSSY) in different stages.

Period	Regression model	R^2	p
Reference period vs. Period-2	$\Delta SSY = -0.135 - 0.850 \times \Delta Dam$	0.886	0.000
Reference period vs. Period-3	$\Delta SSY = -0.067 - 0.659 \times \Delta Dam - 0.081 \times \Delta Pasture$	0.928	0.023
Period-2 vs. Period-3	$\Delta SSY = -0.105 - 0.488 \times \Delta Dam + 0.058 \times \Delta P - 0.129 \times \Delta Pasture$	0.905	0.003

ΔDam and $\Delta Pasture$ are changes in percentage area of check-dams and pasture plantation, respectively. ΔP is changes of annual precipitation over the two compared periods.

Table 5. Pearson correlation coefficients (r) and two-tailed significance test values (p) between sediment yield and annual precipitation (P), number of storms (N_{storm}) and precipitation amount of storms (P_{storm}) during different decades of the CSHC region.

Decades	P		N_{storm}		P_{storm}	
	r	p	r	p	r	p
1960s	0.772	0.015*	0.808	0.008**	0.718	0.029*
1970s	0.266	0.458	0.714	0.020*	0.695	0.026*
1980s	0.775	0.009**	0.633	0.050*	0.527	0.117
1990s	0.865	0.001***	0.591	0.072	0.572	0.084
2000s	0.118	0.715	0.006	0.986	0.138	0.669

***, ** and * indicate the significance levels of 0.001, 0.01 and 0.05, respectively.

Table 6. Regression equations between the decadal sediment coefficient and percentage of the area affected by soil and water conservation measures ($\overline{SC} = -mA_c + n$) in the catchments.
