Dear Editor: Thank you for handling the review process of this manuscript. We appreciate your constructive comments and suggestions. The purpose for proposing the new distribution is elaborated in the introduction section. Particularly, the following sentence has been added in the introduction section:

(Lines 68-70) “The objective of this paper is to unify the SCS-CN method and VIC type of model by proposing a new distribution function for describing the soil water storage capacity.”

The following paragraph has been added in Section 5.2 to elaborate the theoretical base for the PDF:

(Lines 323-336) “This research started with the following research question: if the SCS-CN method is a saturation excess runoff generation model, what is the distribution function of soil water storage capacity? Wang and Tang (2014) showed that equation (37) is derived from the proportionality relationship of SCS-CN method, i.e., equation (38). From the comparison of boundary conditions between SCS-CN method and VIC type of model discussed in Section 4, it is observed that equation (37) does not include initial soil water storage, and the derived one from distribution function will include initial soil water storage (e.g., equation (34)). However, equation (37) can be viewed as the result of $S_0 = 0$; and $W$ for equation (37) can be written as:

$$W = \int_0^P [1 - F(x)] dx$$

(39)

From equation (37), one obtains:

$$W = \frac{P + S_b - \sqrt{(S_b + P)^2 - 2aPS_b}}{a}$$

(40)

Substituting equation (40) into equation (39), one obtains:

$$\frac{P + S_b - \sqrt{(S_b + P)^2 - 2aPS_b}}{a} = \int_0^P [1 - F(C)] dC$$

(41)

Equation (26) is obtained from equation (41).”

The manuscript has been revised and the point-by-point reply to reviewers’ comments are listed below.
Reviewer #1:

Thank you for your constructive comments.

1. Inconsistent numbers ('one' in line 11, but ‘1’ in line 351; similarly for other numbers such as ‘zero’.

   Thanks. “one” has been changed to “1”; and “zero” has been changed to “0”.

2. The motivation of this research is not strong, i.e., why the new distribution function is needed? Or what is the consequences of the mismatch of SCS-CN method and VIC type of model’s boundary conditions. All those questions are not addressed in the introduction part. This is very important, since it can justify the value of this manuscript.

   The following sentence is added in the introduction section:

   (Lines 68-70) “The objective of this paper is to unify the SCS-CN method and VIC type of model by proposing a new distribution function for describing the soil water storage capacity.”

3. With the proposed distribution, when storage index approaches infinity, soil wetting ratio approaches a certain value (≤1) depending on the initial storage. Will this be satisfied in application?

   The following sentence is added in Section 6:

   (Lines 381-382) “(e.g., at the beginning of a rainfall event, runoff is generated at the initially saturated areas, such as wetlands [Gao et al., 2018]).”

4. The assumption used in deriving the probability density distribution is that the spatial distribution of precipitation is assumed to be uniform. This might need further explanation or justification.

   The following sentence is added in Section 5.2:

   (Lines 276-278) “The rainfall in the catchment is assumed to be spatially uniform and the rainfall depth is denoted as P. If the spatial distribution of rainfall is not uniform, the method is applied to sub-catchments where the effect of spatial variability of rainfall is negligible.”
Reviewer #2:

This is a very interesting paper and potentially significant contribution to the hydrology field, particularly semi-distributed rainfall-runoff modeling. The mathematics is quite solid. I do have a few minor comments/questions though.

Thank you for your constructive comments.

1. It is not clear how the author reached the specific probability density function (PDF) (Eqn. 24) since it is not associated with any well-known functions. It’d be better if the author can clarify his reasoning process here.

The following paragraph has been added in Section 5.2:

( Lines 323-336) “This research started with the following research question: if the SCS-CN method is a saturation excess runoff generation model, what is the distribution function of soil water storage capacity? Wang and Tang (2014) showed that equation (37) is derived from the proportionality relationship of SCS-CN method, i.e., equation (38). From the comparison of boundary conditions between SCS-CN method and VIC type of model discussed in Section 4, it is observed that equation (37) does not include initial soil water storage, and the derived one from distribution function will include initial soil water storage (e.g., equation (34)). However, equation (37) can be viewed as the result of $S_0 = 0$; and $W$ for equation (37) can be written as:

$$W = \int_0^P [1 - F(x)] dx$$  \hspace{1cm} (39)

From equation (37), one obtains:

$$W = \frac{P + S_b - \sqrt{(S_b + P)^2 - 2aPS_b}}{a}$$  \hspace{1cm} (40)

Substituting equation (40) into equation (39), one obtains:

$$\int_0^P \frac{1}{a} [1 - F(C)] dC$$  \hspace{1cm} (41)

Equation (26) is obtained from equation (41).”

2. The comparison made between VIC and new distribution have different ranges of $C$ values (Figure 3a and 3b, and Figure 4a and 4b). The $C$ value goes from 0-200 for the new function and 0-50 for VIC.

$C_m$ has been changed to 200 in Figure 3b and Figure 4b.

3. Though it can be seen from Figure 4 that for the new PDF the storage capacity curve has S-shape curve, for the same range of $C$ value (0-50) the new distribution function seems to be no different from $\beta = 1.5$ and $Cm = 50$.

As shown in Figure 3a, when $a<1$, the peak of $f(C)$ occurs at $C=0$; when $a>1$, the peak of $f(C)$ occurs at $C>0$. With the increase of $a$ (when $C>1$), the peak of $f(C)$ occurs at higher value of $C$. The following sentence has been added in Section 5.1:

(Lines 255-257) “The S-shape of CDF (Figure 4a) is more significant with higher value of $a$ (e.g., $a=1.9$). For a smaller value of $a$, the difference between the new PDF and VIC-type of model becomes smaller.”
A new probability density function for spatial distribution of soil water storage capacity

leads to SCS curve number method

Abstract

Following the Budyko framework, soil wetting ratio (the ratio between soil wetting and precipitation) as a function of soil storage index (the ratio between soil wetting capacity and precipitation) is derived from the SCS-CN method and the VIC type of model. For the SCS-CN method, soil wetting ratio approaches one when soil storage index approaches infinity, due to the limitation of the SCS-CN method in which the initial soil moisture condition is not explicitly represented. However, for the VIC type of model, soil wetting ratio equals soil storage index when soil storage index is lower than a certain value, due to the finite upper bound of the power distribution function of storage capacity. In this paper, a new distribution function, supported on a semi-infinite interval \( x \in [0, \infty) \), is proposed for describing the spatial distribution of storage capacity. From this new distribution function, an equation is derived for the relationship between soil wetting ratio and storage index. In the derived equation, soil wetting ratio approaches zero as storage index approaches zero; when storage index tends to infinity, soil wetting ratio approaches a certain value (\( \leq 1 \)) depending on the initial storage. Moreover, the derived equation leads to the exact SCS-CN method when initial water storage is zero. Therefore, the new distribution function for soil water storage capacity explains the SCS-CN method as a saturation excess runoff model and unifies the surface runoff modeling of SCS-CN method and VIC type of model.
Keywords: SCS curve number method, VIC, Xinanjiang, saturation excess, distribution function, soil water storage capacity, soil wetting

1. Introduction

The Soil Conservation Service Curve Number (SCS-CN) method [Mockus, 1972] has been popularly used for direct runoff estimation in engineering communities. Even though the SCS-CN method was obtained empirically [Ponce, 1996; Beven, 2011], it is often interpreted as an infiltration excess runoff model [Bras, 1990; Mishra and Singh, 1999]. Yu [1998] showed that partial area infiltration excess runoff generation on a statistical distribution of soil infiltration characteristics provided similar runoff generation equation as the SCS-CN method. Recently, Hooshyar and Wang [2016] derived an analytical solution for Richards’ equation for ponded infiltration into a soil column bounded by a water table; and they showed that the SCS-CN method, as an infiltration excess model, is a special case of the derived general solution. The SCS-CN method has also been interpreted as a saturation excess runoff model [Steenhuis et al., 1995; Lyon et al., 2004; Easton et al., 2008]. During an interview, Mockus, who developed the proportionality relationship of the SCS-CN method, stated that “saturation overland flow was the most likely runoff mechanism to be simulated by the method” [Ponce, 1996]. Recently, Bartlett et al. [2016a] developed a probabilistic framework, which provides a statistical justification of the SCS-CN method and extends the saturation excess interpretation of the event-based runoff of the method.

Since the 1970s, various saturation excess runoff models have been developed based on the concept of probability distribution of soil storage capacity [Moore, 1985]. TOPMODEL is a well-known saturation excess runoff model based on spatially distributed topography [Beven and Kirkby, 1979; Sivapalan et al., 1987]. To quantify the dynamic change of saturation area during
rainfall events, the spatial variability of soil moisture storage capacity is described by a cumulative probability distribution function in the Xinanjiang model [Zhao, 1977; Zhao et al., 1992] and the Variable Infiltration Capacity (VIC) model [Wood et al., 1992; Liang et al., 1994]. The distribution of storage capacity is described by a power function in these models, which have been used for catchment scale runoff prediction and large scale land surface hydrologic simulations. Bartlett et al. [2016b] unified TOPMODEL, the VIC type of model, and the SCS-CN method by an event-based probabilistic storage framework, which includes a spatial description of the runoff concept of “prethreshold” and “threshold-excess” runoff [Bartlett et al., 2016a].

By applying the generalized proportionality hypothesis from the SCS-CN method to mean annual water balance, Wang and Tang [2014] derived a one-parameter Budyko equation [Budyko, 1974] for mean annual evaporation ratio (i.e., the ratio of evaporation to precipitation) as a function of climate aridity index (i.e., the ratio of potential evaporation to precipitation). As an analogy to the Budyko framework, the SCS-CN method and the VIC type of model at the event scale can be represented by the relationship between soil wetting ratio, defined as the ratio between soil wetting and precipitation, and soil storage index which is defined as the ratio between soil wetting capacity and precipitation.

In this paper, the functional forms for soil wetting ratio versus soil storage index are compared between the SCS-CN model and the VIC/Xinanjiang-type of model. Based on the comparison, a new distribution function is proposed for describing the soil water storage capacity in the VIC type of model so that the objective of this paper is to unify the SCS-CN method and VIC type of model by proposing a new distribution function for describing the soil water storage capacity. In section 2, the SCS-CN method is presented in the form of Budyko-
type framework with two parameterization schemes. In section 3, the VIC type of model is presented in the form of Budyko-type framework. In section 4, the SCS-CN method is then compared with the VIC type of model from the perspectives of number of parameters and boundary conditions (i.e., the lower and upper bounds of soil storage index). In section 5, the proposed new distribution function is introduced and compared with the power distribution of VIC type of model; and a modified SCS-CN method considering initial storage explicitly is derived from the new distribution function. Conclusions are drawn in section 6.

2. SCS curve number method

In this section, the SCS-CN method is described in the form of surface runoff modeling and then is presented for infiltration modeling in the Budyko-type framework. The initial storage at the beginning of a time interval (e.g., rainfall event) is denoted by $S_0$ [mm], and the maximum value of average storage capacity over the catchment is denoted by $S_b$ [mm]. The storage capacity for soil wetting for the time interval, $S_p$ [mm], is computed by:

$$S_p = S_b - S_0$$  \hspace{1cm} (1)

The total rainfall during the time interval is denoted by $P$ [mm]. Before surface runoff is generated, a portion of rainfall is intercepted by vegetation and infiltrates into the soil. This portion of rainfall is called initial abstraction or initial soil wetting denoted by $W_i$ [mm]. The remaining rainfall ($P - W_i$) is partitioned into runoff and continuing soil wetting. This competition is captured by the proportionality relationship in the SCS-CN method:

$$\frac{W - W_i}{S_p - W_i} = \frac{Q}{P - W_i}$$  \hspace{1cm} (2)

where $W$ [mm] is the total soil wetting; $W - W_i$ is continuing wetting and $S_p - W_i$ is its potential value; $Q$ [mm] is surface runoff; and $P - W_i$ is the available water and interpreted as
the potential value of $Q$. Since rainfall is partitioned into total soil wetting and surface runoff, i.e., $P = W + Q$, surface runoff is computed by substituting $W = P - Q$ into equation (2):

$$Q = \frac{(P - W_i)^2}{P + S_p - 2W_i}$$  \hspace{1cm} (3)

This equation is used for computing direct runoff in the SCS-CN method.

The SCS-CN method can also be represented in terms of soil wetting ratio ($\frac{W}{P}$).

Substituting equation (3) into $W = P - Q$ and dividing $P$ on both sides, the soil wetting ratio equation is obtained:

$$\frac{W}{P} = \frac{\frac{S_p}{P} \frac{W_i^2}{P^2}}{1 + \frac{S_p}{P} - 2 \frac{W_i}{P}}$$  \hspace{1cm} (4)

Climate aridity index is defined as the ratio between potential evaporation and precipitation. In climate aridity index, both available water supply and water demand are determined by climate.

$$\Phi_{sc} = \frac{S_p}{P}$$  \hspace{1cm} (5)

A similar dimensionless parameter for the ratio between the maximum soil storage capacity and mean rainfall depth of rainfall events was defined in Porporato et al. [2004]. In soil storage index, water demand is determined by soil and available water supply is determined by climate.

Substituting equation (5) into equation (4), the soil wetting equation for the SCS-CN method is obtained:

$$\frac{W}{P} = \frac{\Phi_{sc} \frac{W_i^2}{P^2}}{1 + \Phi_{sc} - 2 \frac{W_i}{P}}$$  \hspace{1cm} (6)

Two potential schemes for parameterizing the initial wetting in equation (6) are discussed in the following sections.

2.1. Parameterization scheme 1: ratio between initial wetting and storage capacity
The initial wetting is usually parameterized as the ratio between initial wetting and storage capacity in the SCS-CN method. The potential for continuing wetting is called potential maximum retention and is denoted by \( S_m = S_p - W_i \). \( S_m \) is computed as a function of curve number which is dependent on land use/land cover and soil permeability. The ratio between \( W_i \) and \( S_m \) in the SCS curve number method is denoted by \( \lambda = \frac{W_i}{S_p - W_i} \), and then the ratio between initial soil wetting and storage capacity is computed by:

\[
\frac{W_i}{S_p} = \frac{\lambda}{1 + \lambda} \quad (7)
\]

The value of \( \lambda \) varies in the range of \( 0 \leq \lambda \leq 0.3 \), and a value of 0.2 is usually used [Ponce and Hawkins, 1996]. Substituting equation (7) into equation (6) leads to:

\[
\frac{W}{P} = \frac{1 - \left(\frac{\lambda}{1 + \lambda}\right)^2 \Phi_{sc}}{1 - 2\lambda + \Phi_{sc} - 1} \quad (8)
\]

Equation (8) is plotted in Figure 1 for \( \lambda = 0.1 \) and 0.3. As we can see, the range of \( \Phi_{sc} \) is dependent on the parameter \( \lambda \). Since \( W_i \leq P \), \( \Phi_{sc} \) is in the range of \( \left[0, 1 + \frac{1}{\lambda}\right] \). Equation (8) satisfies the following boundary conditions: \( \frac{W}{P} \to 0 \) as \( \Phi_{sc} \to 0 \); and \( \frac{W}{P} \to 1 \) as \( \Phi_{sc} \to \frac{\lambda + 1}{\lambda} \). When \( \lambda \to 0 \), equation (8) becomes:

\[
\frac{W}{P} = \frac{1}{1 + \Phi_{sc}^{-1}} \quad (9)
\]

Equation (9) is the lower bound for \( \frac{W}{P} \) based on this parameterization scheme.

**2.2. Parameterization scheme 2: ratio between initial wetting and total wetting**

In order to avoid the situation that the range of \( \Phi_{sc} \) is dependent on the parameter \( \lambda \), we can use the following parameterization scheme [Chen et al., 2013; Tang and Wang, 2017]:

\[
\varepsilon = \frac{W_i}{W} \quad (10)
\]

Substituting equation (10) into equation (6), we can obtain the following equation:
We can solve for $\frac{W}{P}$ from equation (11):

$$
\frac{W}{P} = \frac{\Phi_{sc} - \varepsilon W^2}{1 + \Phi_{sc} - 2\varepsilon W} \tag{11}
$$

Equation (12) has the same functional form as the derived Budyko equation for long-term evaporation ratio [Wang and Tang, 2014; Wang et al., 2015]. Equation (12) satisfies the following boundary conditions: $\frac{W}{P} \to 0$ as $\Phi_{sc} \to 0$; and $\frac{W}{P} \to 1$ as $\Phi_{sc} \to \infty$. Based on equation (10), the range of $\varepsilon$ is $[0, 1]$, and $\varepsilon = 1$ corresponds to the upper bound (Figure 1). Equation (12) becomes equation (9) as $\varepsilon \to 0$, and it is the lower bound. Figure 1 plots equation (12) for $\varepsilon = 0.1$ and 0.3. Due to the dependence of the range of $\Phi_{sc}$ on the parameter $\lambda$ in the first parameterization scheme, the second parameterization scheme is focused on in the following sections.

In the SCS-CN method, the soil wetting ratio is a function of soil storage index with a parameter for describing initial wetting. The average wetting capacity at the catchment scale is used for computing soil storage index; but the spatial variability of wetting capacity is not represented in the SCS-CN method.

3. Saturation excess runoff model

The spatial variability of soil water storage capacity is explicitly represented in the saturation excess runoff models such as VIC and Xinanjiang. In these models, the spatial variation of point-scale storage capacity ($C$) is represented by a power function:

$$
F(C) = 1 - \left(1 - \frac{C}{C_m}\right)^\beta \tag{13}
$$
where $F(C)$ is the cumulative probability, i.e., the fraction of catchment area for which the storage capacity is less than $C$ [mm]; and $C_m$ [mm] is the maximum value of point-scale storage capacity over the catchment. The water storage capacity includes vegetation interception, surface retention, and soil moisture capacity; $\beta$ is the shape parameter of storage capacity distribution and is usually assumed to be a positive number. $\beta$ ranges from 0.01 to 5.0 as suggested by Wood et al. [1992]. The storage capacity distribution curve is concave down for $0 < \beta < 1$ and concave up for $\beta > 1$. The average value of storage capacity over the catchment is equivalent to $S_b$ in the SCS-CN method, and it is obtained by integrating the exceedance probability of storage capacity $S_b = \int_0^{C_m} (1 - F(x)) \, dx$:

$$S_b = \frac{C_m}{\beta + 1}$$

(14)

Similarly, for a given $C$, the catchment-scale storage $S$ [mm] can be computed [Moore, 1985]:

$$S = S_b \left[ 1 - \left( 1 - \frac{C}{C_m} \right)^{\beta + 1} \right]$$

(15)

To derive wetting ratio as a function of soil storage index, the initial storage at the catchment scale is parameterized by the degree of saturation:

$$\psi = \frac{S_0}{S_b}$$

(16)

Recalling equation (1) and the definition of soil storage index (i.e., equation (5)), we obtain:

$$\frac{S_b}{P} = \frac{\Phi_{sc}}{1 - \psi}$$

(17)

The value of $C$ corresponding to the initial storage $S_0$ is denoted as $C_0$, and $S_0 = S_b \left[ 1 - \left( 1 - \frac{C_0}{C_m} \right)^{\beta + 1} \right]$ is obtained by substituting $S_0$ and $C_0$ into equation (15). When $P + C_0 \geq C_m$,
each point within the catchment is saturated and soil wetting reaches its maximum value, i.e.,

\[ W = S_p \].

Substituting \( C_0 = C_m - C_m \left(1 - \frac{S_0}{S_b}\right)^\frac{1}{\beta+1} \) into \( P + C_0 \geq C_m \), we obtain:

\[ \Phi_{sc} \leq b \text{ where } b = (\beta + 1)^{-1}(1 - \psi)\frac{\beta}{\beta+1} \]  

(18)

Therefore, this condition is equivalent to:

\[ \frac{W}{P} = \Phi_{sc} \text{ when } \Phi_{sc} \leq b \]  

(19)

Next, we will derive \( \frac{W}{P} \) for the condition of \( \Phi_{sc} > b \). The storage at the end of the modeling period (e.g., rainfall-runoff event) is denoted as \( S_1 \), which is computed by:

\[ S_1 = S_b \left[1 - \left(1 - \frac{P + C_0}{C_m}\right)^{\beta+1}\right] \]  

(20)

Since \( W = S_1 - S_0 \), wetting is computed by:

\[ W = S_b \left[1 - \left(1 - \frac{P + C_0}{C_m}\right)^{\beta+1}\right] - S_0 \]  

(21)

From equation (21), we obtain (see Appendix A for details):

\[ \frac{W}{P} = \Phi_{sc} \left[1 - \left(1 - b\Phi_{sc}^{-1}\right)^{\beta+1}\right] \text{ when } \Phi_{sc} > b \]  

(22)

The limit of equation (22) for \( \Phi_{sc} \rightarrow \infty \) can be obtained (see Appendix B for details):

\[ \lim_{\Phi_{sc} \rightarrow \infty} \frac{W}{P} = (1 - \psi)\frac{\beta}{\beta+1} \]  

(23)

Equations (19) and (22) provide \( \frac{W}{P} \) as a function of \( \Phi_{sc} \) with two parameters (\( \psi \) and \( \beta \)). Figure 2 plots equations (19) and (22) for \( \psi = 0 \) and 0.5 when \( \beta = 0.2 \) and 2. As we can see, \( \frac{W}{P} \) decreases as \( \beta \) increases for given values of \( \psi \) and \( \Phi_{sc} \); and \( \frac{W}{P} \) decreases as \( \psi \) increases for given values of \( \beta \) and \( \Phi_{sc} \), implicating that soil wetting ratio decreases with the degree of initial saturation under a given soil storage index.

4. Comparison between SCS-CN model and VIC type of model
The SCS-CN model with the parameterization of ratio between initial wetting and total wetting is compared with the VIC type of saturation excess runoff model. In sections 2 and 3, we derived \( \frac{W}{P} \) as a function of \( \Phi_{sc} \) based on the SCS-CN method and the VIC type of model, which uses a power function to describe the spatial distribution of storage capacity. The SCS-CN method is a function of storage capacity \( S_p \); but the VIC type of model is a function of storage capacity \( S_p \) and the degree of initial saturation \( \frac{S_0}{S_b} \). As a result, the function of \( \frac{W}{P} \sim \frac{S_p}{P} \) for the SCS-CN method has only one parameter (\( \varepsilon \)), but it has two parameters (\( \beta \) and \( \psi \)) for the VIC type of model.

Table 1 shows the boundary conditions for the relationships between \( \frac{W}{P} \) and \( \Phi_{sc} \) from the SCS-CN method and the VIC type of model. The lower boundary of the SCS-CN method with parameter \( \varepsilon \) is \( \frac{W}{P} \to 0 \) as \( \Phi_{sc} \to 0 \). However, for the VIC type of model, \( \frac{W}{P} = \Phi_{sc} \) when \( \Phi_{sc} \leq b \).

For the SCS-CN method, \( W \) reaches its maximum (\( S_p \)) when rainfall reaches infinity; while for the VIC type of model, \( W \) reaches its maximum value (\( S_p \)) when rainfall reaches a finite number (\( C_m - C_0 \)). In other words, for the SCS-CN method, the entire catchment becomes saturated when rainfall reaches infinity; while for the VIC type model, the entire catchment becomes saturated when rainfall reaches a finite number.

As shown in Table 1, the upper boundary of the SCS-CN method (with parameter \( \varepsilon \)) is 1. However, for the VIC type of model, the upper boundary is \( (1 - \psi)^{\frac{\beta}{\beta + 1}} \) instead of 1. This is due to the effect of initial storage in the VIC type of model. When initial storage is 0 (i.e., \( \psi = 0 \)), the wetting ratio \( \frac{W}{P} \) for the VIC type of model has the same upper boundary condition as the SCS-CN method.

5. **Unification of SCS-CN method and VIC type of model**
Based on the comparison between the SCS-CN method and VIC type of model, a new
distribution function is proposed in this section for describing the spatial distribution of soil
water storage capacity, which unifies the SCS-CN method and VIC type of model. As discussed
in section 4, the upper boundary condition of the SCS-CN model (i.e., $\frac{W}{P} \to 1$ as $\Phi_{sc} \to \infty$) does
not depend on the initial storage. This upper boundary condition needs to be modified by
including the effect of initial storage so that the limit of $\frac{W}{P}$ as $\Phi_{sc} \to \infty$ is dependent on the
degree of initial saturation like the VIC type of model. However, the lower boundary condition
of the VIC model needs to be modified so that the lower boundary condition follows that $\frac{W}{P} \to 0$
as $\Phi_{sc} \to 0$ like the SCS-CN method. Through these modifications, the SCS-CN method and the
VIC type of saturation excess runoff model can be unified from the functional perspective of soil
wetting ratio.

Based on the comparison one may have the following questions: 1) Can the SCS-CN
method be derived from the VIC type of model by setting initial storage to zero? 2) If yes, what
is the distribution function for soil water storage capacity? Once we answer these questions, a
modified SCS-CN method considering initial storage explicitly can be derived as a saturation
excess runoff model based on a distribution function of water storage capacity, and it unifies the
SCS-CN method and VIC type of model. In this section, a new distribution function is proposed
for describing the spatial variability of soil water storage capacity, from which the SCS-CN
method is derived as a VIC type of model.

5.1. A new distribution function

The probability density function (PDF) of the new distribution for describing the spatial
distribution of water storage capacity is represented by:
where $C$ is point-scale water storage capacity and supported on a positive semi-infinite interval 
($C \geq 0$); $a$ is the shape parameter and its range is $0 < a < 2$; and $\mu$ is the mean of the 
distribution (i.e., the scale parameter). Figure 3a plots the PDFs for five sets of shape and scale 
parameters. When $a \leq 1$, the PDF monotonically decreases with the increase of $C$, i.e., the peak 
of PDF occurs at $C = 0$; while when $a > 1$, the peak of PDF occurs at $C > 0$ and the location of 
the peak depends on the values of $a$ and $\mu$. For comparison, Figure 3b plots the PDF for VIC 
model:

$$f(C) = \frac{(2-a)\mu^2}{\left[(C+\mu)^2-2a\mu C\right]^{3/2}}$$  \hspace{1cm} (24)$$

As shown by the solid black curve in Figure 3b, when $0 < \beta < 1$, $f(C)$ approaches infinity as
$C \to C_m$. It is a uniform distribution when $\beta = 1$. The peak of PDF occurs at $C = 0$ when $\beta > 1$. 
Therefore, the peak of PDF for VIC model occurs at $C = 0$ or $C_m$.

The cumulative distribution function (CDF) corresponding to the proposed PDF is
obtained by integrating equation (24):

$$F(C) = 1 - \frac{1}{a} + \frac{c+(1-a)\mu}{a\sqrt{(C+\mu)^2-2a\mu C}}$$  \hspace{1cm} (26)$$

Figure 4a plots the CDFs corresponding to the PDFs in Figure 3a. For comparison, Figure 4b
plots the CDFs corresponding to the PDFs in Figure 3b. The storage capacity distribution curve
for the proposed distribution is concave up for $a \leq 1$ and S-shape for $a > 1$ (Figure 4a); while
the storage capacity distribution curve for VIC model is concave up for $\beta > 1$ and concave down
for $0 < \beta < 1$ (Figure 4b). The S-shape of CDF (Figure 4a) is more significant with higher
value of $a$ (e.g., $a=1.9$). For a smaller value of $a$, the difference between the new PDF and VIC-
type of model becomes smaller. Therefore, the proposed distribution can fit the S-shape of
cumulative distribution for storage capacity which is observed from soil data [Huang et al., 2003], but the power distribution of VIC type of model is not able to fit the S-shape of CDF.

5.2. Deriving SCS-CN method from the proposed distribution function

The soil wetting and surface runoff can be computed when equation (26) is used to describe the spatial distribution of soil water storage capacity in a catchment. The average value of storage capacity over the catchment is the mean of the distribution:

$$\mu = S_b$$  \hspace{1cm} (27)

For a given $C$, the catchment-scale storage $S$ can be computed by $S = \int_{0}^{C} [1 - F(x)] dx$ [Moore, 1985]. From equation (26), we obtain:

$$S = \frac{C + S_b - \sqrt{(C + S_b)^2 - 2aS_bC}}{a}$$  \hspace{1cm} (28)

For a rainfall-runoff event, the average initial storage at the catchment scale is denoted as $S_0$ and the corresponding value of $C$ is denoted as $C_0$. Substituting $S_0$ and $C_0$ into equation (28), we obtain:

$$S_0 = \frac{C_0 + S_b - \sqrt{(C_0 + S_b)^2 - 2aS_bC_0}}{a}$$  \hspace{1cm} (29)

Dividing $S_b$ in both-hand sides of equation (29), we obtain:

$$m = \frac{\psi(2 - a\psi)}{2(1 - \psi)}$$  \hspace{1cm} (30)

where $\psi = \frac{S_0}{S_b}$ is defined in equation (16), and $m$ is defined as:

$$m = \frac{C_0}{S_b}$$  \hspace{1cm} (31)

The rainfall in the catchment is assumed to be spatially uniform and the rainfall depth is denoted as $P$. If the spatial distribution of rainfall is not uniform, the method is applied to sub-
catchments where the effect of spatial variability of rainfall is negligible. The average storage at
the catchment scale after infiltration is computed by substituting $C = C_0 + P$ into equation (28):

$$S_1 = \frac{C_0 + P + S_b - \sqrt{(C_0 + P + S_b)^2 - 2a S_b (C_0 + P)}}{a}$$  \hspace{1cm} (32)

The soil wetting is computed as the difference between $S_1$ and $S_0$:

$$W = \frac{P + \sqrt{(C_0 + S_b)^2 - 2a S_b C_0} - \sqrt{(C_0 + P + S_b)^2 - 2a S_b (C_0 + P)}}{a}$$  \hspace{1cm} (33)

Dividing $P$ on the both-hand sides of equation (33) and substituting equation (31), we obtain:

$$\frac{W}{P} = \frac{1 + \left(\frac{S_b}{P}\right) \sqrt{(m+1)^2 - 2am} - \left(\frac{1 + \left(\frac{S_b}{P}\right)^2}{(m+1)^2 - 2am} - 2a \frac{S_b}{P}\right)^2 - 2a \frac{S_b}{P}}{a}$$  \hspace{1cm} (34)

Substituting equation (17) into equation (34), we obtain:

$$\frac{W}{P} = \frac{1 + \left(\frac{m+1)^2 - 2am \frac{\Phi_{sc}}{1-\psi} \Phi_{sc} \right) - \left(\frac{1 + \left(\frac{m+1)^2}{1-\psi} \Phi_{sc} \right)^2 - 2am \left(\frac{\Phi_{sc}}{1-\psi} \Phi_{sc} \right)^2 - 2a \frac{\Phi_{sc}}{1-\psi} \Phi_{sc} \right)}{a}$$  \hspace{1cm} (35)

Figure 5 plots equation (35) for $\psi = 0$, 0.4, and 0.6 when $a = 0.6$ and 1.8. As we can see, $\frac{W}{P}$ increases with $a$ for given values of $\psi$ and $\Phi_{sc}$; and $\frac{W}{P}$ decreases with $\psi$ for given values of $a$ and $\Phi_{sc}$, which is consistent with the VIC model and implicates that soil wetting ratio decreases with the degree of initial saturation under a storage index. As shown in Figure 5, equation (35) satisfies the lower boundary of SCS-CN method and the upper boundary of the VIC model. Specifically, equation (35) satisfies the following boundary conditions (see Appendix C for details) shown in Table 1:

$$\lim_{\Phi_{sc} \to 0} \frac{W}{P} = 0$$  \hspace{1cm} (36-1)

$$\lim_{\Phi_{sc} \to \infty} \frac{W}{P} = \frac{\sqrt{(m+1)^2 - 2am + a - m - 1}}{a \sqrt{(m+1)^2 - 2am}}$$  \hspace{1cm} (36-2)

When the effect of initial storage is negligible (i.e., $\psi = 0$), $\frac{S_b}{P} = \Phi_{zc}$ from equation (17) and $m = 0$ from equation (30). Then, equation (35) becomes:
\[
\frac{W}{P} = 1 + \frac{S_b}{P} \sqrt{\left(1 + \frac{S_b}{P}\right)^2 - 2\alpha \frac{S_b}{P}} \tag{37}
\]

Equation (37) is the same as equation (12) with \( a = 2\varepsilon (2 - \varepsilon) \). We can obtain the following equation from equation (37) (see Appendix D for detailed derivation):

\[
\frac{Q}{P - \varepsilon W} = \frac{W - \varepsilon W}{S_b - \varepsilon W} \tag{38}
\]

where \( \varepsilon W \) is defined as initial abstraction (\( W_i \)) in the SCS-CN method. Since \( S_b = S_p \) when \( \psi = 0 \), equation (38) is the same as equation (2), i.e., the proportionality relationship of SCS-CN method.

Equation (35) is derived from the VIC type model by using equation (26) to describe the spatial distribution of soil water storage capacity. From this perspective, equation (35) is a saturation excess runoff model. Since equation (35) becomes the SCS-CN method when initial storage is negligible, equation (35) is the modified SCS-CN method which considers the effect of initial storage on runoff generation explicitly. Therefore, the new distribution function represented by equation (26) unifies the SCS-CN method and VIC type of model.

Bartlett et al. [2016a] developed an event-based probabilistic storage framework including a spatial description of “prethreshold” and “threshold-excess” runoff; and the framework has been utilized for unifying TOPMODEL, VIC and SCS-CN [Bartlett et al., 2016b]. The extended SCS-CN method (SCS-CNx) from the probabilistic storage framework is derived given the following assumptions: 1) the spatial distribution of rainfall is exponential; 2) the spatial distribution of soil moisture deficit is uniform; and 3) the spatial distribution of storage capacity is exponential. When “prethreshold” runoff is zero (i.e., there is only threshold-excess or saturation excess runoff), the SCS-CNx method leads to the SCS-CN method without the initial abstraction term (i.e., there is no \( \varepsilon W \) term in equation (38)). In this paper, the new
probability distribution function is used for storage capacity in the VIC model in which the spatial distribution of precipitation is assumed to be uniform. The obtained equation for saturation excess runoff leads to the exact SCS-CN method as shown in equation (38).

This research started with the following research question: if the SCS-CN method is a saturation excess runoff generation model, what is the distribution function of soil water storage capacity? Wang and Tang (2014) showed that equation (37) is derived from the proportionality relationship of SCS-CN method, i.e., equation (38). From the comparison of boundary conditions between SCS-CN method and VIC type of model discussed in Section 4, it is observed that equation (37) does not include initial soil water storage, and the derived one from distribution function will include initial soil water storage (e.g., equation (34)). However, equation (37) can be viewed as the result of \( S_0 = 0 \); and \( W \) for equation (37) can be written as:

\[
W = \int_0^P [1 - F(x)] dx \tag{39}
\]

From equation (37), one obtains:

\[
W = \frac{P + S_b - \sqrt{(S_b + P)^2 - 2aPS_b}}{a} \tag{40}
\]

Substituting equation (40) into equation (39), one obtains:

\[
\frac{P + S_b - \sqrt{(S_b + P)^2 - 2aPS_b}}{a} = \int_0^P [1 - F(C)] dC \tag{41}
\]

Equation (26) is obtained from equation (41).

5.3. Surface runoff of unified SCS-CN and VIC model

From the unified SCS-CN and VIC model (i.e., equation (34)), surface runoff \( Q \) can be computed as:

\[
Q = \frac{(a-1)P - S_b\sqrt{(m+1)^2 - 2am + \sqrt{[P+(m+1)S_b]^2 - 2amS_b^2 - 2aS_bP}}}{a} \tag{3942}
\]

16
The parameter $m$ is computed by equation (30) as a function of $\psi$ and $a$. Equation (4239) represents surface runoff as a function of precipitation ($P$), average soil water storage capacity ($S_b$), shape parameter of storage capacity distribution ($a$), and initial soil moisture ($\psi$). Figure 6 plots equation (3942) under different values of $P$, $S_b$, $a$, and $\psi$. Figure 6a shows the effects of $S_b$ and $\psi$ on rainfall-runoff relationship with given shape parameter of $a=1.9$. The solid lines show the rainfall-runoff relations with zero initial storage ($\psi=0$); and the dashed lines show the rainfall-runoff relations with $\psi=0.2$. Given the same amount of precipitation and storage capacity, wetter soil ($\psi=0.2$) generates more surface runoff than drier soil ($\psi=0$); and the difference of runoff is higher for watersheds with larger average storage capacity. Figure 6b shows the effects of $S_b$ and $a$ on rainfall-runoff relationship with given initial soil moisture ($\psi=0.2$). The solid lines show the rainfall-runoff relations for $a=1.9$; and the dashed lines show the rainfall-runoff relations for $a=1.2$. As we can see, the shape parameter affects the runoff generation significantly for watersheds with larger average storage capacity.

In the SCS-CN method, surface runoff is computed as $Q = \frac{(P-0.2S_b)^2}{P+0.8S_b}$. The effect of initial soil moisture on runoff is considered implicitly by varying the curve number for normal, dry and wet conditions depending on the antecedent moisture condition. In the unified SCS-CN model shown in equation (3942), the effect of initial soil moisture is explicitly included through $\psi$, which is the ratio between average initial water storage and average storage capacity. In the SCS-CN method, the value of initial abstraction $W_i$ is parameterized as a function of average storage capacity, i.e., $W_i = 0.2S_b$. In the unified SCS-CN model shown in equation (3942), $W_i$ is dependent on the shape parameter $a$. Therefore, the unified SCS-CN model extends the original SCS-CN method for including the effect of initial soil moisture explicitly and estimating the parameter for initial abstraction.
6. Conclusions

In this paper, the SCS-CN method and the saturation excess runoff models based on distribution functions (e.g., VIC model) are presented in terms of soil wetting (i.e., infiltration). Like the Budyko framework, the relationship between soil wetting ratio and soil storage index is obtained for the SCS-CN method and the VIC type of model. It is found that the boundary conditions for the obtained functions do not fully match. For the SCS-CN method, soil wetting ratio approaches 1 when soil storage index approaches infinity, and this is due to the limitation of the SCS-CN method, i.e. the initial soil moisture condition is not explicitly represented in the proportionality relationship. However, for the VIC type of model, soil wetting ratio equals soil storage index when soil storage index is lower than a certain value, and this is due to the finite bound of the distribution function of storage capacity.

In this paper, a new distribution function, which is supported by \( x \in [0, \infty) \) instead of a finite upper bound, is proposed for describing the spatial distribution of soil water storage capacity. From this new distribution function, an equation is derived for the relationship between soil wetting ratio and storage index, and this equation satisfies the following boundary conditions: when storage index approaches zero, soil wetting ratio approaches zero; when storage index approaches infinity, soil wetting ratio approaches a certain value (\( \leq 1 \)) depending on the initial storage (e.g., at the beginning of a rainfall event, runoff is generated at the initially saturated areas, such as wetlands [Gao et al., 2018]). Meanwhile, the model becomes the exact SCS-CN method when initial storage is negligible. Therefore, the new distribution function for soil water storage capacity explains the SCS-CN method as a saturation excess runoff model, and unifies the SCS-CN method and the VIC type of model for surface runoff modeling.
Future potential work could test the performance of the proposed new distribution function for quantifying the spatial distribution of storage capacity by analyzing the spatially distributed soil data. On one hand, the distribution functions of probability distributed model [Moore, 1985], VIC model, and Xinanjiang model could be replaced by the new distribution function and the model performance would be further evaluated. On the other hand, the extended SCS-CN method (i.e., equation (35)), which includes initial storage explicitly, could be used for surface runoff modeling in SWAT model, and the model performance would be evaluated.

The author would like to thank University of Central Florida Faculty Excellence for their support during his sabbatical leave. This paper is theoretical and does not contain any supplementary data.

Appendix A

The following equation is obtained by dividing P on both sides of equation (21):

\[
\frac{W}{P} = \frac{S_b - S_0}{P} - \frac{C_0}{C_m} \left( 1 - \frac{P + C_0}{C_m} \right)^{\beta + 1}
\]  

(A1)

Substituting \( \frac{C_0}{C_m} = 1 - \left( 1 - \frac{S_0}{S_b} \right)^{\frac{1}{\beta + 1}} \) into equation (A1), we obtain:

\[
\frac{W}{P} = \frac{S_b - S_0}{P} - \frac{S_b}{P} \left( 1 - \frac{P}{C_m} \left[ 1 - \left( 1 - \frac{S_0}{S_b} \right)^{\frac{1}{\beta + 1}} \right]^{\beta + 1} \right)
\]  

(A2)

Substituting equation (14) into equation (A2),

\[
\frac{W}{P} = \frac{S_b - S_0}{P} - \left( \left( \frac{S_b - S_0}{P} \right)^{\frac{1}{\beta + 1}} - \left( \frac{S_b}{P} \right)^{\frac{\beta}{\beta + 1}} \right)^{\beta + 1}
\]  

(A3)
Substituting equations (5) and (17) into (A3), we obtain:

\[
\frac{W}{p} = \Phi_{\text{sc}} - \left( \Phi_{\text{sc}} \frac{1}{\beta+1} - \frac{\Phi_{\text{sc}}}{\beta+1} \right)^{\beta+1} \tag{A4}
\]

which leads to:

\[
\frac{W}{p} = \Phi_{\text{sc}} \left[ 1 - \left( 1 - b\Phi_{\text{sc}}^{-1} \right)^{\beta+1} \right] \tag{A5}
\]

where \( b \) is defined in equation (18).

**Appendix B**

\[
\lim_{\Phi_{\text{sc}} \to \infty} \frac{W}{p} = \lim_{\Phi_{\text{sc}} \to \infty} \Phi_{\text{sc}} \left[ 1 - \left( 1 - b\Phi_{\text{sc}}^{-1} \right)^{\beta+1} \right] \tag{B1}
\]

The right hand side of equation (B1) is re-written as:

\[
\lim_{\Phi_{\text{sc}} \to \infty} \Phi_{\text{sc}} \left[ 1 - \left( 1 - b\Phi_{\text{sc}}^{-1} \right)^{\beta+1} \right] = \lim_{\Phi_{\text{sc}} \to \infty} \frac{1 - (1 - b\Phi_{\text{sc}}^{-1})^{\beta+1}}{\Phi_{\text{sc}}^{-1}} \tag{B2}
\]

Since \( \lim_{\Phi_{\text{sc}} \to \infty} \left( 1 - b\Phi_{\text{sc}}^{-1} \right)^{\beta+1} = 0 \) and \( \lim_{\Phi_{\text{sc}} \to \infty} \Phi_{\text{sc}}^{-1} = 0 \), we apply the L'Hospital's Rule,

\[
\lim_{\Phi_{\text{sc}} \to \infty} \frac{1 - (1 - b\Phi_{\text{sc}}^{-1})^{\beta+1}}{\Phi_{\text{sc}}^{-1}} = \lim_{\Phi_{\text{sc}} \to \infty} b(\beta + 1) \left( 1 - b\Phi_{\text{sc}}^{-1} \right)^{\beta} \tag{B3}
\]

Since \( \lim_{\Phi_{\text{sc}} \to \infty} \left( 1 - b\Phi_{\text{sc}}^{-1} \right)^{\beta} = 1 \), the limit for \( \frac{W}{p} \) is obtained:

\[
\lim_{\Phi_{\text{sc}} \to \infty} \frac{W}{p} = b(\beta + 1) \tag{B4}
\]

Substituting equation (18) into (B4), we obtain:

\[
\lim_{\Phi_{\text{sc}} \to \infty} \frac{W}{p} = (1 - \psi) \frac{\beta}{\beta+1} \tag{B5}
\]

**Appendix C**
\[ \lim_{\Phi_{sc} \to \infty} \frac{W}{P} = \lim_{\Phi_{sc} \to \infty} \frac{1 + \sqrt{(m+1)^2 - 2am}}{1 - \psi} \Phi_{sc} - \sqrt{(1 + \frac{m+1}{1 - \psi} \Phi_{sc})^2 - 2am - (\Phi_{sc})^2 - 2a \Phi_{sc}} \]  \hfill (C1)

Multiplying \( 1 + \sqrt{(m+1)^2 - 2am} \Phi_{sc} + \sqrt{(1 + \frac{m+1}{1 - \psi} \Phi_{sc})^2 - 2am - (\Phi_{sc})^2 - 2a \Phi_{sc}} \) to the denominator and numerator of the right hand side, equation (C1) leads to:

\[ \lim_{\Phi_{sc} \to \infty} \frac{W}{P} = \frac{1}{a} \lim_{\Phi_{sc} \to \infty} \frac{\sqrt{2(m+1)^2 - 2am} - 2(1 + \frac{m+1}{1 - \psi} \Phi_{sc})^2 - 2a + 2a \Phi_{sc}}{2 - \sqrt{2(m+1)^2 - 2am} \Phi_{sc} + \sqrt{(1 + \frac{m+1}{1 - \psi} \Phi_{sc})^2 - 2am - (\Phi_{sc})^2 - 2a \Phi_{sc}}} \]  \hfill (C2)

Dividing \( \Phi_{sc} \) in the denominator and numerator, we obtain:

\[ \lim_{\Phi_{sc} \to \infty} \frac{W}{P} = \frac{1}{a(1 - \psi)} \lim_{\Phi_{sc} \to \infty} \frac{\sqrt{2(m+1)^2 - 2am - 2am - 2a(1 + \frac{m+1}{1 - \psi} \Phi_{sc})^2 - 2a} - 2a + 2a \Phi_{sc}}{2 - \sqrt{2(m+1)^2 - 2am} \Phi_{sc} + \sqrt{(1 + \frac{m+1}{1 - \psi} \Phi_{sc})^2 - 2am - (\Phi_{sc})^2 - 2a \Phi_{sc}}} \]  \hfill (C3)

Therefore, the limit of \( \frac{W}{P} \) as \( \Phi_{sc} \to \infty \) is:

\[ \lim_{\Phi_{sc} \to \infty} \frac{W}{P} = \frac{\sqrt{(m+1)^2 - 2am + a - m - 1}}{a \sqrt{(m+1)^2 - 2am}} \]  \hfill (C4)

### Appendix D

Substituting \( a = 2\epsilon(2 - \epsilon) \) into equation (37), one can obtain:

\[ \frac{W}{P} = \frac{1 + \frac{S_b}{P} - \sqrt{(1 + \frac{S_b}{P})^2 - 4\epsilon(2 - \epsilon) \frac{S_b}{P}}}{2\epsilon(2 - \epsilon)} \]  \hfill (D1)

Equation (D1) is the solution of the following quadratic function:

\[ \epsilon(2 - \epsilon) \left( \frac{W}{P} \right)^2 - \left( 1 + \frac{S_b}{P} \right) \frac{W}{P} + \frac{S_b}{P} = 0 \]  \hfill (D2)

Multiplying \( P^2 \) at the both-hand sides of equation (D2), equation (D2) becomes:

\[ \epsilon(2 - \epsilon)W^2 - (P + S_b)W + S_bP = 0 \]  \hfill (D3)

Equation (D3) can be written as the following one:

\[ \frac{P - W}{P - \epsilon W} = \frac{W - \epsilon W}{S_b - \epsilon W} \]  \hfill (D4)
Substituting $Q = P - W$ into equation (D4), we obtain the proportionality relationship of SCS-CN method:

$$\frac{Q}{P - \epsilon W} = \frac{W - \epsilon W}{S_b - \epsilon W}$$
